PHILIP B. STEWART.

Colorado Springs, Col.

[The various plans of swarm control you propose have all been tried. There are two objections. First, they call for too much work; second, they do not always succeed, and are, therefore, risky. I would suggest that you follow Dr. Miller's book, "Forty Years Among the Bees," very closely. The Dudley tube is an adaptation of Langdon's device on the entrance, and I imagine it will not last long.]

My experience with comb honey leads me to say that certain points are very important, and need to be emphasized.

1. Good shade; 2. Plenty of air current during hot weather; 3. A space below the frames for the bees to cluster; 4. As few "contraptions" in the hive and supers as possible; 5. Young queens.

Let the box hives swarm once. Fifteen days afterward, drive all the bees out and add them to the swarm, killing all the virgin queens. What is left is empty comb, fit only for the wax-extractor.

The nearer you make a comb-honey hive like an extracted, the better it will work. There is no royal road to comb-honey production, and plans have to be modified to suit seasons and localities —W. K. M.]

CAN UNFINISHED SECTIONS BE USED FOR EARLY SPRING FEEDING?

I was intending to ask you the advisability of putting in unfinished sections early for feed; but I see in the Jan. 15th GLEANINGS, p. 83, its disadvantages as well as advantages. I should like to know if I should put a few in each hive early in April, even before any pollen is to be found, if the bees would take the hint and use it for feed. To prevent the cooling of the hives I think there would be room to put back the cushions on

top of the super containing the unfinished sections, as I use the large chaff hives.

AMELIA J. CULVER.

Mt. Lebanon, N. Y.

[The bees might or might not take the honey out of the sections and use the same for brood-rearing. A good deal would depend upon circumstances. The sections should be so given as not to leave a lot of empty space for the bees to warm up. Your proposal to put back the cushions is correct in theory and practice.—ED.]

HOW TO PACK A FEW COLONIES OF BEES FOR THE WINTER.

Many small bee-keepers having from one to a dozen colonies allow them to remain on the stand all winter without any protection, and in the spring wonder why so many of the bees died. A plan by which their bees can be wintered safer and cheaper outdoors than if placed in a cellar is this: After the honey season is over, and the supers have been emptied and cleaned, I place them back again on the hives with the section slats left in. I do this early enough—about the last of October—that the bees may have time to wax things down tight between the edges of the super and brood-chamber. When very

cold weather comes on, and the bees have quit flying, I place them in a row east and west, with front to the south, and about a foot apart. I now fill each super full of old rags, pieces of burlap, or even torn-up newspapers, finishing with a quilt of burlap, and on this I place the cover proper, snug and tight. The straw (prairie hay is better) is then packed in between tight to the top of the hive and over all and behind; and at the ends I put the straw three feet deep, finishing with a cover of tar-paper tacked to two 2x4's or scantlings the desired length, one placed in front, the other back, with slope enough to carry off water, and thus keep the packing dry. I leave the bees as they are, quite late in the spring until rains and cold chilly days gives way to warm settled weather. I then remove the winter protection and space the hives a proper distance apart again. I might also add that I place a board in front on sunny days to prevent bees from flying out and perishing. The engraving may help to explain my plan.

Tecumseh, Neb.

CYRUS DOUGLAS.

[This shed would be better if the bees were made to enter on the lower (or opposite) side of it. This leaves the high side for the apiarist, so that he can handle the hives from behind instead of in front.—W. K. M.]

TESTING THE WEIGHT OF HIVES IN SPRING; "HEFTING" NOT A SAFE GUIDE.

On March 20 of last year, when I "hefted" my hives they were fully as heavy as when packed for winter. Imagine my surprise to find them, April 10, at the point of starvation. While there is no doubt that considerable honey was gathered during March, the queens seemed to think that summer had arrived, and that it was time to be up and doing. The result was, hives full of brood, and I had hefted brood instead of honey. This leads me to the conclusion that, while the hefting plan may do in the fall when you know there is little or no brood in the hive, it is not a safe guide in the spring, especially after such winters as the past has been here in the South.

Tupelo, Miss.

J. D. ROWAN.

POSITION OF CLUSTER IN WINTER SEEN THROUGH A GLASS COVER.

This is the third winter that I have wintered colonies in hives with double glass covers so that I could look in at any time without disturbing the bees or letting the cold air in on them. These colonies are in pairs with only a thin division-board between them; quilts over and around them, and one outer case over all.

The winter cluster does not form near the entrance, as some have said, but in the warmest part of the brood-nest, next to the thin division-board, the top of the cluster being above the brood-frames. There is a half inch space between the brood-frames and glass.

The entrance to these hives is very small—not to exceed one square inch; and I know by actual trial that the entrance can be closed for weeks at a time, and do no harm to the bees if the weather continues cold and the bees remain in that semi-dormant state which is natural for them in winter, with the temperature of the cluster many degrees lower than when active. In this state I am sure they need very little honey, very little air, and they lose very little vitality. But if roused from this state by any cause they must have air or there will be trouble. With an entrance equal to one square inch kept clear, I have found that they are perfectly safe through the winter.

I have always kept a thermometer on top of the double-glass cover of one of these colonies, and this has never shown a temperature lower than 38 degrees, and this with a temperature outside of 12 below zero. In

ordinary weather it indicates a temperature of 42 to 48 degrees. There are two thicknesses of glass and a dead-air space of half an inch between the cluster and thermometer.

I should like to ask Mr. Doolittle how he reconciles these facts with the statement he has made, that "the heat of a cluster is confined within the cluster or crust of bees," and does not warm the space outside of the cluster.

O. S. REXFORD.

Winsted, Ct.

[Many reports as well as repeated observations year after year convince us that, early in the winter, the cluster of bees will be found up in front of the hive. As the winter advances and the stores are consumed, the cluster works backward. If you repeat your experiences for a year or more yet, we think you will find what we say is true. We agree exactly with you as to the size of the entrance.—Ed.]

THE VALUE OF A TWO-INCH SPACE UNDER THE FRAMES.

Twenty-five years ago I worked my bees with an entrance two inches deep, full width of the hive, having special deep rims for all hives having two supers, according to the plan explained by Dr. Miller, p. 290, Mar. 1. After all these years of following the crowd with a half-way compromise that has cost me hundreds of dollars I am going back to the deeper space beneath the frames for strong colonies at all seasons, only contracting the entrance to exclude mice in winter. Dr. Miller should put nothing in to prevent the bees building comb down. For every ounce built below the bottom-bars the bees will store 5 lbs. more surplus in the supers. They will store pollen at the bottom, and go higher up with the honey, owing to their fore-sense of robbery.

While the bees are building any bits of comb beneath they will bring their combs above tight down to the bottom-bars, if only $\frac{1}{2} \times 3 \times 4$ -inch bars are used. They will not build so much burr-comb with a surplus of wax if the extra space is allowed. The extra wax pays for itself if saved, as thousands of colonies in Cuba are run for wax alone, as they pay better to produce wax than an inferior grade of extracted honey. They are not likely to get the swarming fever, as they do with the pent-up space beneath ordinary hives. More air beneath enables them to stay in a second super in the heat of the day; and the deeper cluster gives more uniform heat for the brood and super above it at all times.

F. DANZENBAKER.

Norfolk, Va.

DUCKS IN THE APIARY.

On p. 42, Jan. 1, I see your remarks about ducks in an apiary. You say you never experienced any trouble from them. Just saw a patch of white clover in or near your beeyard, and then let your ducks in and see how they "do" the bees. I had but one stand left over last winter. The rest were winter-killed. The one that came through

had a queen which you sent me the year before, but it had only a handful of bees in the spring. It increased fast in the spring, and made preparations for swarming. Just then my young ducks took to the clover and after the bees so that all of them died. They ate the bees so fast that they had to run for water.

G. KUNKE.

Panoka, Canada, Jan. 20, 1908.

HONEY PASTE FOR STICKING SMALL LABELS TO TIN.

We have been putting up honey in tin cans and buckets, and have tried all kinds of paste for sticking labels to tin (including flour paste as recommended by Mr. W. H. Laws). We had but poor success until we tried mixing a small quantity of honey with our dextrine and vinegar paste, which ended our trouble in that line.

We have been putting up and selling some six to ten tons of extracted honey per year these last few years. We also tried rubbing the buckets with a rag wet with vinegar, as recommended by N. E. France; but while it helped somewhat, many of the labels would drop off as soon as dry.

These other pastes might do if a label is used that will go clear around the bucket and even lap over a little; but they will not hold a small label.

Mix dextrine and vinegar to the consistency to suit, then add about 2 oz. of honey to the pint of paste. Don't make the mistake of putting too much honey in or the labels will have a greasy appearance and will not dry right. It requires more honey in a dry atmosphere than in a wet one. Such paste will keep in either a warm or cold climate.

Ebensburg, Pa. F. J. STRITTMATTER.

TROUBLE IN MAKING INCREASE:

I have just read an article by Mr. E. W. Alexander, on page 896, on the right way to increase. This matter of increase has been and still is a hard problem for me to solve, I started in to increase 100 colonies, but have lost nearly half the season by their building up so slowly. I had a great many poor and unfertile queens. I am now starting a few nuclei and also the two-queen system with queen-excluders between the hive and cap. I have had a good many years' experience, but have had more trouble with increase this year than ever before. There has been no scarcity of honey at any time, but the queens seem to be slow about laying. My method is exactly the same as Alexander's. Has anybody anything better to offer?

R. E. ZIMMERMANN.

Fresno, Cal., Aug. 3, 1907.

[The trouble in your case, we should say, was poor queens. Better queen, or two ordinary queens to the colony, separated by excluders, would obviate your difficulty to a great extent. As you are trying the two-queen plan we shall be glad to have you report.—Ed.]

STIMULATIVE FEEDING DURING THE COLD SPRING WEATHER TO KEEP THE HIVES WARM.

My experiments in feeding in spring were of great value, especially in the cold rainy weather we had last spring. I feed with an inverted beer-bottle through a hole in the hive-cover. Just draw a piece of cotton cloth four inches square over the neck of the bottle and insert it in the hole. This keeps the bees active, and they will keep the entire hive warm, and rear all brood without loss; whereas if they have an abundance of sealed honey in combs they become dormant, or nearly so, and cluster. If the inclement weather continues for two or more days, much sealed brood dies; and the first warm day the hive-front will be covered with hundreds of dead bees with the head formed and legs started, while all unsealed brood is eaten as fast as it is exposed to the outside of the cluster. This may seem incredible, but they invariably do so when cold or starving. The queen, if a good one, will lay eggs at all times when there is honey coming in, but not when the honey is stored in the combs.

When we can keep the queen laying, and all brood reared, the problem of strong colonies is easily solved.

Sonora, Cal.

A. D. HEROLD.

[We question very much whether feeding in early spring serves to keep the colony warm because of the stimulation induced. If the weather is chilly enough to keep a colony back, feeding at such a time would only tend to aggravate matters. Of course, if a colony is running very short, and is liable to starve, then if no combs of sealed stores are available one would be obliged to feed.—Ed.]

WATERING BEES IN THE HIVES TO PREVENT THEM FROM FLYING OUT ON CHILLY DAYS FOR WATER.

On page 1498, Dec. 1, Dr. Miller gives us some excellent advice about watering bees. It is my opinion that the most important part of the article is that which relates to the early spring, when the bees are compelled to risk all in order to obtain water for the brood.

I had an Alexander feeder under each hive—some to feed, others to stimulate. There would be times of days in a stretch when the bees would not break cluster to go to the feed at the rear and bottom end of the hive with the prevailing cold winds which swept our prairies.

One fine morning last spring, on going to the tank where the boys were watering their horses, I noticed that the whole surface of the tank was covered with struggling bees drowning in the water. This was not a pleasant sight to behold when fully half of the hives in the apiary were empty and half of the rest were in a weak condition; so I took a pail of water, threw a handful of sugar into it, and gave each colony a pint in the Alexander feeders that were under the hive. In half an hour there were no bees to be seen about the tank. While we may af-

ford to let our bees hustle for their drink during summer time we surely can not afford to do so in early spring. Just slip an Alexander feeder under each hive and give them what they want to drink at home.

Moorland, Ia.

J. P. BLUNK.

[Attention has been drawn to this before; but it was stated at that time that the moisture from the breath of the bees, condensed on the inside of the hives in chilly weather, would give the bees all the water they would need for brood-rearing. Whether true or not, we should be glad to hear from any one who may have any fact to offer. We are of the opinion that many bees are lost in the spring in the quest outdoors for water when the weather is bad.—Ed.]

QUEENS SUPERSEDED IN WINTER.

I have read in GLEANINGS that bees would not supersede queens in winter. I am sending you two queens just hatched, and there were several more cells in the colony. The same thing happened last winter in my yard in January.

GEORGE GROVER.

Trenton, N. J., Feb. 11.

[While it is true that supersedure usually does not take place in winter, yet if a failing queen leaves eggs or young brood the bees will raise queen-cells as at other times, providing it be not too cold. If it were severe weather there would, of course, be no eggs. In that case the colony, if it survived, would be found queenless in the spring. But if the queen dies the colony is likely to die also.—Ed.]

CONCRETE WATERING-TROUGH FOR BEES.

In order to water bees, make a concrete vat 8 feet long, 6 wide, and 6 inches deep; then fill it with sand and small gravel, and it is ready for the water. I have used this three years with good results—no drowned bees as there are around a tank. I keep the sand and gravel drawn up from the center a little so the water can be reached longer. A bucket of water now and then will keep the gravel moist.

B. F. SPAFFORD.

Morning Sun, Iowa.

[This is a good suggestion. If no creek be near, moist gravel should be provided.—Ed.]

ENTRANCE-GUARD TO PREVENT ROBBING.

When robbing is going on, contract the entrance of the robbed colony down to one-fourth the usual size, and place an entrance-guard over it. It will be a bold robber that will enter after this is done.

Pittsfield, Ill.

GEO. B. DUFF.

[The scheme of applying an entrance-guard to check robbing we consider excellent.—Ed.]

LIQUEFYING HONEY IN AN INCUBATOR.

In regard to an article on page 145, about liquefying honey with hot air, I came to the following idea, which I think would make the job easy, and at the same time do it at very

little cost, and but little attention would be required from the bee-keeper. Just have the machine made with a thermostat, and also supplied with a thermometer, as our modern incubators are arranged, only the egg-chamber (which would be our honey-chamber) should be about twenty inches deep. It would probably be good to have doors on both sides so that the honey-cans might be more easily put in and removed. There should also be double doors, the outside one of wood, while the inside one would be of glass; and the doors should either work side-wise or upward, so as to be more out of the way. The size of the machine will have to depend on the quantity of the honey to be liquefied; but a machine taking eight or twelve 60-lb. cans would be large enough for the average bee-keeper. This machine would probably require a little larger lamp than an incubator of the same dimensions; but if honey will liquefy within 24 hours at a temperature of 100° it surely will consume but very little oil compared with the labor saved; and I think an even temperature of 110 or probably 125° would not spoil the flavor of the honey. I do not think it necessary to have the caps of the honey-cans removed.

New Braunfels, Tex. W. C. CONRADS.

[We have already been experimenting somewhat along these lines. See editorial on this subject elsewhere.—ED.]

PAINTING THE EDGES OF HIVE-BODIES.

In the painting of hive-bodies and supers I wonder how many bee-keepers paint the edges as well as the sides. If you have not tried this, try it and see what a difference it makes when you come to clean them. The unpainted edges well coated with propolis are next to impossible to clean, while with the painted edges it is a very easy matter, as the propolis can not penetrate the wood. It is also important that the edges of hive-bodies resting on the bottom-boards be well painted, as they are nearest the ground, and the unpainted surface would soon turn black and decay. It will pay to paint the floors of the bottom-boards and the under side of the roofs; in fact, the hive should be completely covered with paint excepting only the inside walls. Use nothing but the best grades of pure white lead and oil. Keep the hives well covered with paint, and there is no reason why they should not last a lifetime.

Nisbet, Pa.

GRANT STANLEY.

[Our correspondent is entirely right. When we paint, let us make a thorough job. We find it pays.—ED.]

QUEENS SUPERSEDED ON THE DOOLITTLE NON-SWARMING PLAN.

I have had this experience so far with the Doolittle non-swarming plan. If the colonies are not extra strong, or if the queen is poor, the bees will supersede their queens. In fact, they nearly all superseded their queens

for me. The Doolittle plan will work, but I think the swarming should be done just at the commencement of a good flow, and the colonies must be very strong.

Sunnyside, Wash

S. K. CLOVER.

OUR HOMES

by A. I. ROOT

I came not to send peace but a sword.—MATT. 10:34.

O full of all subtilty and all mischief, thou child of the devil, thou enemy of all righteousness, wilt thou not cease to pervert the ways of the Lord?—ACTS 13:10.

Some time ago I was speaking here in these Home Papers of the wonderful discoveries that were coming so thick, and I said it almost made one stand still and wonder what great thing was coming next. What new and startling gift had God in store for us that should shake and astonish the world? A bright and successful young farmer, a good spiritual man, stopped me in the road a few days after and asked if I did not have faith to believe the next great thing would be somewhere along in the line of spiritual or moral reforms. So far radium, wireless telegraphy, flying-machines, etc., seemed to have little bearing in the way of rebuking sin and crime. I confessed to him I had been feeling a little sad to think these new discoveries had, so far, so little bearing on uplifting the morals of the world that we might almost doubt that they came from the hand of God—moving pictures, for instance. My friend (Adam Lister, Medina, O.), however, declared it as his belief that the next great thing to shake and astonish the world would be along in the line of spiritual things, and possibly something that would reprove and rebuke sinful humanity.

About the same time a good friend from away off on the Pacific coast wrote me something as follows:

Brother Root:—You wonder what great thing is coming next. Well, I am glad to be able to tell you. The Lord Jesus Christ is coming soon to receive his people and to "rebuke the devourer.*" Shall we not all make haste and be ready to receive him?

Well, this thing has been on my mind ever since the suggestion came from these two friends; but I must confess I was so dull, and had so little faith, I did not recognize that the Lord Jesus Christ had come until I saw in the daily papers that our beloved Ohio had, by an overwhelming majority in both House and Senate, passed the county local-option law. I knew we had been sending some good men to make our laws and to represent the people; but after witnessing defeat after defeat by the rum power in the years that are passed, it was one of my greatest

* I will rebuke the devourer for your sakes, and he shall not destroy the fruits of your ground.—MAL. 2:10.

"happy surprises" when I saw not only *Ohio* but a great lot of the Southern States actually taking the lead. I have given you an account of the fight in the Senate some time ago when I happened to be present. A very bright young attorney from Cincinnati was speaking. He was well educated, handsome, talented, and a magnificent orator; but he was evidently in the employ of the millionaire brewers. He declared he was a temperance man, and in favor of the measure, and was exceedingly anxious to help it along, and I for a time was tempted to think him sincere. The way in which he took defeat after defeat brought forth my admiration; and after it was explained so I could see through his ingenious tricks I could imagine him turning to his employers and saying, "There! didn't I work hard for you? Did I leave any stone unturned to defeat these fanatics?" The "fanatics," however, saw through the "sheep's clothing," and his hypocrisy was rebuked, and buried with a shout. The Christian men and scholars we have been sending to represent us said in action what Paul said to the sorcerer, and just of late the good people all over our land have been saying to all of the great army of brewers and their hirelings: "Thou child of the devil, wilt thou not cease to pervert the right ways of the Lord?"

God has been indeed sending the Holy Spirit, even the spirit of Christ Jesus, down to a sinful world, and, as a result, our churches, Sunday-schools, Endeavor societies, etc., have been working in harmony and furnishing *good men* to be on hand and to be looking after the framing of our laws. The "drawing cards" the liquor party have employed so long, together with their money, seem to be playing out—especially this trick of "amendments," in order to "make our law better" (?). See the following from the *Cleveland Plain Dealer* of Feb. 27:

After three hours of verbal fireworks the House of Representatives this afternoon passed the bill by a vote of 79 to 36. Temperance advocates broke into song at the conclusion of the long fight. The leaders of the movement say the law, which will go into effect Sept. 1, will be the means of wiping saloons out of 75 out of the 88 counties of the State.

Every attempt to defeat or amend the measure was emphatically repudiated. The bill was passed exactly in the form in which it came from the Senate. The big majority persistently refused to consent to a change so much as the dotting of an *i* or the crossing of a *t*.

Representative Foster, of Findlay, attempted to inject an amendment changing palpable errors in construction, grammar, and spelling.

"Is this bill so sacred that this legislature can not be trusted to correct gross errors?" demanded Foster. The answer was a shout that buried the amendment beyond recall.

The vote against the bill was almost entirely from members representing counties with large cities. The rural members solidly supported the measure as it stood, irrespective of party. It was another demonstration that liquor interests have lost the control they have claimed so long over the Democratic party. The vote for and against the bill was one of geographical location.

The editor of our Medina paper says Medina County will be among the first in the State to be made dry by the new law. The county-seat (Medina) has been dry for over 20 years. Now, shall we not all join in a

friendly strife to see which county and State shall be first to say, in the plain language of Paul, "O child of the devil, thou enemy of all righteousness, wilt thou not cease to pervert the right ways of the Lord?"

When the saloons are cleaned out it will be an easy matter to say pretty much the same thing to the grafters who are stealing the money from our hard-working people in other ways. The love for temperance, purity, and "a square deal" is in the air; and it is *because* the spirit of Christ Jesus is getting into men's hearts in a way that was never known before.

We have a jail here in Bradentown; and, even if Manatee is a dry county I was surprised to find on my first visit eleven inmates, and most of them (in fact, I may say all) through drink. Two are in for murder, and the murder was done while on a drunken spree just before *Christmas*. The sheriff says the liquor comes from Tampa; but there is strong talk now of making even Tampa, with its 40,000 people, dry.

Last Sunday morning I said to my class in jail, "Boys, I suppose you will all rejoice with me that Ohio has passed the county local-option law, by a big majority."

A big burly colored man at my elbow replied, "Mr. Root, I ain't a very good man, I admit; but I try to be honest and tell the truth. I can't rejoice with you. The most satisfaction I have ever got out of any thing in this world is drink."

I looked him over a little and then replied: "My friend, if you want the privilege of getting drunk with a clear conscience you certainly would accord the same to everybody else. Suppose we all do your way."

He replied that he could not be responsible for any one but himself.

Sometimes we often find something in a private letter that is better than many things written for publication, and I want to close with a sort of postscript from a letter just received from my son, E. R. It gives you a glimpse of him you might not get otherwise.

Dear Father:—I have just read your letter in regard to the pledge to the Anti-saloon League. I am placing the same before John. I feel that no money has ever been given to any cause that has been productive of larger results than that which we give to the Anti-saloon League. The showing is getting to be something tremendous; and, just think! it was my old classmate, Howard Russell, who started the movement, and it was you and Mr. Metcalf who held the thing on its feet until it could strike a blow.

The Roots especially ought to feel some pride in having been, as I might say, charter members of this magnificent organization that has helped produce such wonderful results all over the United States. Butler, Indiana, Mabel's old home, has just gone dry, and all the towns near by are now having a battle royal. The thing is going all over the United States, and it looks now as if even you would see the day when the saloons will be banished from all except our large cities and even then they will be crowded off by themselves. The way the great journals are pouring hot shot into the saloon business is very encouraging. Witness what *Collier's* is going to do as per enclosure. It has already published some *splendid* editorials.

May the Lord be praised that it was my privilege, and the privilege of the Root Co., to say, through the Anti-saloon League, "Thou child of the devil," etc., "*the hand of the Lord is upon thee.*"

LUMBER

BARGAIN PRICES.

A wonderful opportunity is offered you to buy lumber and building supplies every kind at **Prices that will save you big money.** Such a chance seldom occurs. Lumber for your house, church, barn, meeting house, crib, store, factory, and in fact, buildings of every kind. We can furnish absolutely everything needed in construction material. Have your carpenter or builder make a complete list of everything you require, including Lumber, Sash Doors, Nails, Roofing, Siding, Ceiling, in fact, anything you may need in building material or merchandise of any kind.

Send us your Lumber Bill for Our Estimate.

We bought at Manufacturers' Sale over 50,000,000 Feet of all kinds of Lumber and Finishing Material. We are making special concessions, to those who buy at once. Even if you have no use for this lumber at once, it will pay you to buy now. Our prices will save you 30 to 50 per cent.

We cheerfully invite inspection of our Lumber stock and will be glad to have you come to our warehouse and yards at Chicago, see the lumber we are offering, and you will recognize that it is all what we say of it; make your own selection and see it loaded. It is not necessary to come to Chicago; we can easily sell you by mail. We can quickly convince you of the wisdom of placing an order with us. Just send us your lumber bill, and we will easily "Show You." On application we will send copies of letters from customers who have bought. They saved money why can't you? Write us to-day. **WE PURCHASED EVERY EXPOSITION, INCLUDING THE \$50,000,000 "ST. LOUIS WORLD'S FAIR."** Send for our Free 500 page Catalog No. C.H. 688. It quotes low prices on Furniture, Household Goods, Building Material, Machinery and Supplies.

Paint Without Oil

Remarkable Discovery that Cuts Down the Cost of Paint Seventy-five Per Cent.

A Free Trial Package is Mailed to Every One Who Writes.

A. L. Rice, a prominent manufacturer of Adams, N. Y., has discovered a process of making a new kind of paint without the use of oil. He calls it Powdrpaint. It comes in the form of a dry powder, and all that is required is cold water to make a paint weather-proof, fire-proof, and as durable as oil paint. It adheres to any surface, wood, stone, or brick, spreads and looks like oil paint and costs about one-fourth as much.

Write to Mr. A. L. Rice, Manufacturer, 202 North St., Adams, N. Y., and he will send you a free trial package, also color-card and full information showing you how you can save a good many dollars. Write to day

IRON AGE TOOLS

Make Your Paint Money Buy Satisfaction

PAINT satisfaction means the working—spreading—covering—lasting qualities of the paint.

There's neither satisfaction nor economy in *cheap* paints—they crack and peel and blister—won't wear.

And hand mixed lead-and-oil paint is little better.

But your money buys unfailing satisfaction when you get "High Standard" Paint—It's made of best materials—and

ground-and-mixed into a perfectly uniform paint-liquid by machinery.

Lowe Brothers
High Standard
Liquid Paint

Then there's thirty-five years of paint-making experience back of it.

That's why "High Standard" Paint covers more—and wears from two to four years longer than other paint, and costs less.

Write for our free booklet, "Attractive Homes and How to Make Them."

BARGAINS IN BEE-FIXTURES.

We offer at reduced prices quite a list of goods located at various points, and chiefly of styles not at present listed in our catalog. You may find here something which you can use to advantage. Orders may be sent direct to Medina, or in some cases direct to the dealer or branch house where the goods are on hand. In ordering, be sure to mention that you saw it in "Bargain Notice" in GLEANINGS.

THE A. I. ROOT CO., Medina, O.

EXTRACTORS.

At Apopka, Orange Co., Fla., one six-frame Cowan extractor for L. frame, which has been used in all about 30 days; was sold five years ago, and is the old-style chain reversing type; sold new for \$30.00. We offer this for \$17.00, free on board at shipping-point.

At Medina, O., three eight-frame Root Automatic extractors which have been to Cuba and returned; have been somewhat rusted and corroded by salt air; well cleaned up, and in good condition. With ordinary hand-power gear we will sell at \$32.00 each; regular price \$40.00. With power gear and belt complete, without engine, \$36.00; regular price, \$45.00.

No. 4 Novice extractors at Mechanic Falls, Me.; also at Chicago, Ill.; also Des Moines, Iowa; new stock, but an over supply, offered at \$7.75 each; regular price, \$8.50.

No. 15 Cowan extractor at Mechanic Falls, Me.; new machines in good condition as put out three years ago; offered at \$11.00 each.

DADANT UNCAPPING-CAN at St. Louis, Mo. and in New York city; offered at \$7.75 each; new stock in good condition, somewhat shop-worn.

GERMAN WAX-PRESS at St. Louis, Mo., and in New York city; also at Medina, O. These are not of the latest pattern, but good machines in good condition; offered at \$9.00 each; regular price, \$12.00.

BOARDMAN SOLAR WAX-EXTRACTOR at Des Moines, Iowa, and at New York city, in good condition at \$6.00. Regular price, \$7.50. Also at New York a Doolittle solar wax-extractor at \$3.25.

PARTS OF HIVES.

DANZ. NAILLESS COVERS, made of three pieces, tongued and put together with paint in joints and crate-staples over joint at each end, then a galvanized channel steel cleat at each end; the same style as our metal-bound super-cover, only made of $\frac{3}{8}$ -in. lumber. Special price to close out, 20 cts. for 8-frame; 22 cts. 10-frame, which is $\frac{3}{4}$ regular price.

The A. I. Root Co., Syracuse, N.Y., 30 D-8 and 66 D-10
The A. I. Root Co., Philadelphia, Pa. 70 D-8 and 500 D-10
The A. I. Root Co., Medina, O. . . . 200 D-8 and 300 D-10

COMBINED BOTTOM AND HIVE-STAND. This is a very convenient and serviceable hive-bottom which sold at the same price as the hive-cover, or was

included instead of the regular bottom at 5 cts. per hive extra; can be had from the following places in 8 or 10 frame size as listed, at the price of the regular bottom, in lots of 5 or more, 20 cts. each, 8-frame; 22 cts. each, 10 frame.

M. H. Hunt & Son, Redford, Mich., 30 C-8 and 20 10
The A. I. Root Co., Syracuse, N. Y., 30 C-8 and 100 C-10
The A. I. Root Co., Philadelphia, Pa., 100 C-8 and 10 C-10

The A. I. Root Co., Philadelphia, Pa., 200 " at 20 cts. ea.

W. S. Pouder, Indianapolis, Ind., 60 nailed at 20 cts. ea.

M. H. Hunt & Son, Redford, Mich., 75 in flat, 10 cts. ea.

TEN-FRAME DOVETAILED HIVE-BODIES with molded-top Hoffman frames; no division-board; listed as 5-10.

With The A. I. Root Co., New York city, 300, offered in regular crates of 5 at 60 cts. each, or \$3.00 per crate; lots of 50 or more at 50 cts.

The A. I. Root Co., St. Paul, Minn., have a lot of Danz. hives and supers; also ten-frame Dovetailed hives, nailed and painted, second hand, in good condition, which they will sell at a special price. Correspond direct with them.

STANDARD ROOT SMOKERS. We have here at Medina something less than 100 of these smokers, which have been to Cuba and returned. They are somewhat rusted but may be made serviceable by one not too particular for appearances. Will sell them at 50 cts. each, or \$5.00 per dozen; by mail, 25 cts. each extra.

FREE! 50 lbs. Comb Foundation FREE!

WEED'S NEW-PROCESS COMB FOUNDATION.

PRIZES GIVEN AWAY

ABSOLUTELY FREE IN A CONTEST.

FIRST PRIZE—25 lbs. Comb Fdn.

THIRD PRIZE—5 lbs. Comb Fdn.

SECOND " —10 lbs. Comb Fdn.

FOURTH " —5 lbs. Comb Fdn.

FIFTH PRIZE—5 lbs. Comb Fdn.

THE ABOVE PRIZES will be given absolutely free to those who will make the largest number of words out of the letters found in the name "Toepperwein." The letters may be used over as many times as desired, but in no single word oftener than found in the name "Toepperwein." Only words found in Webster's dictionary are admitted. The words must all be plainly written in columns, and numbered.

This contest is absolutely free to any one and anywhere. It is a fair contest, and one has the same chance as the other. These contests are very instructive, and just the thing for schoolchildren to pass the evenings. The contest will close May 1, 1908, and all lists with words must then be in, and in May 15th GLEANINGS the results will be published, giving the names of the winners and all the words of the one who wins the first prize. The winners have the privilege of choosing any grade of foundation. We feel confident that the winners will be highly pleased with the prizes, as the comb foundation is as fine and perfect as any machinery can make, and is made right here in our factory out of this clear Southern beeswax.

A MAN'S DISPOSITION

is, without doubt, seriously affected by the climatic conditions which surround him.

ARE YOU PLEASANTLY LOCATED?

Are you shut in by the ice and snow of a rigorous winter, with naught but a cheerless sky to gaze upon? What of your lands now? Covered with snow? How about your stock? Have to be kept housed and fed?

The farmers in our territory are plowing, their stock grazing on the hillsides, and in the famous Manatee section growers are shipping their products to Northern markets, receiving remarkable prices for the same, due to the season.

Our lands are just as fertile as yours, produce just as much and at a time when prices are the best. It's a duty you owe yourself and family to look into this.

CLIMATE IS A MOST IMPORTANT FACTOR in connection with the profits, as well as pleasure, to be derived from your location.

Wouldn't you like to be pleasantly situated, surrounded by climatic conditions which permit work to be carried on the entire year, and where the struggle for existence against the elements of a frozen North is not known?

The climate in the six States traversed by our line is unsurpassed anywhere, and the profits being derived by those who only a few years ago were battling with the rigors of winter in a northern location is evidence of the value of our lands. Do you expect to remain where you are and keep up the struggle? Why not come down into southern sunshine and be pleasantly located, while at the same time you are deriving big profits from your crops?

OUR LITERATURE IS FREE. The "Seaboard Magazine," prepared especially for the benefit of parties contemplating a change of location, will help you. Let us put your name on our mailing-list. Drop us a postal to-day.

HOWKINS & RUSH
241 BULL ST. SAVANNAH, GA.

The Hand System

TO satisfy a number of customers we are now making hives to suit the above system, just as the inventor himself uses them. These are not listed in our regular spring catalog, and are not kept in stock at any of our agencies. All orders will be filled from Medina. If ordered early enough, however, they can be forwarded to any one of our branches for redistribution. If you are going to try a few of these hives the coming season, we earnestly urge you to order early before the rush season comes on.

PRICE LIST OF HAND DIVISIONAL HIVE AND PARTS.

We have had numerous calls for divisional hives just as Mr. Hand uses them. We will not list them in our catalog for the coming season, but will make them up to supply on special order, to those who desire to try them, at prices in table below. The outside dimensions being nearly the same as the regular Dovetailed hive, the regular covers and bottoms may be used.

Each section is 19 $\frac{1}{2}$ in. long, 5 $\frac{1}{2}$ in. deep outside; upper portion of side removable with clamps to hold it in place. Sections used are 4 $\frac{1}{2}$ x4 $\frac{1}{2}$ x1 $\frac{1}{2}$ plain, split three sides. Furnished in both eight and ten frame size.

HOME AGAIN.

Will the friends who want to write A. I. Root personally, bear in mind that he expects to be in Medina once more, shortly after April 1?

HONEY WANTED.

We are in the market for comb honey in Danzenbaker sections, either clover or basswood. Only fancy or A No. 1 grades are required. If you have any on hand which meets these requirements, please communicate at once, stating quantity and price.

MAPLE SUGAR AND SYRUP.

The maple-groves in this vicinity have produced an abundant crop of choice sweets this season; and while we have not yet secured very much of it, we expect to be well supplied as soon as the roads improve and producers have time to bring it to market. Fancy first-run syrup brings \$1.15 per gallon; six gallons or over, \$1.10, while good ordinary syrup can be had at \$1.00 per gallon; six gallons or over, 95 cts.; twenty-five gallons and upward at 90 cts. Maple sugar is worth 12 to 15 cts. per lb., according to quality and quantity. We should be pleased to hear from those interested, stating quantity you can use, when we will quote you.

A BARGAIN IN DANZ. SUPERS AND SHIPPING-CASES.

We offer at a special bargain 120 Danzenbaker ten-frame supers, nailed and painted, filled with section-holders, Hyde-Scholl "M" fences, sections with full sheets of foundation. They have been used, but are nearly new and in good condition. Such supers new are listed in our catalog at \$1.75 each, yet we offer this lot crated and on board cars at Floresville, Texas, at 50 cts. each for the lot, and will throw in 1000 4x5 sections to make good any in the lot which may be broken or missing. In lots of not less than ten the price would be 60 cts. each; 50 at 55 cts. each as they are crated and loaded on cars. There are also 400 shipping-cases to hold 20 4x5 sections in the crates as shipped from the factory, which we would sell at \$5.00 per crate of 50, or \$9.00 per 100 for the lot—that is, \$140 cash for goods worth new at carload prices over \$340. This surely is a bargain for any one desiring to produce fancy comb honey with equipment that can not be excelled for the purpose. They are not in the right locality for comb-honey production, but should work excellently in some other locality. Send your orders here to Medina.

CLOVER SEED OF ALL KINDS SCARCE

Judging from the very high prices prevailing for clover seeds, the supply must be scarce. Mammoth medium and alsike are selling at \$3.00 and upward per bushel. White clover is not so high. This can be furnished at \$10.00 per bushel. Alfalfa is also high, and brings \$12.00 per bushel, while there is no change in crimson.

We have had an unusual demand for sweet-clover seed, and have but very little of it left. We shall be in the market for several tons of seed from this season's crop; and when the time comes to gather it we should be pleased to correspond with those who can supply the seed of both white and yellow, hulled or unhulled. If any of our readers have any seed on hand to dispose of we should be pleased to hear from them, naming quantity and price. We still have some yellow hulled seed which we offer, while it lasts at 25 cts. per lb.; 10 lbs., \$2.30; 25 lbs., \$5.50; 100 lbs., \$21.00. We have some white seed, nearly all hulled, but containing a small per cent of unhulled seed. Price 3 cts. per lb. less than the above. We can also supply a limited quantity of unhulled seed at 17 cts. per lb.; 10 lbs., \$1.50; 25 lbs. or over, at 14 cts.; by mail, 10 cts. per lb. extra for any of the above to pay for postage and packing.

THE ALEXANDER BEE-VEIL.

We have secured, for making a bee-veil of wire cloth, a special weave of cloth having 8 meshes to the inch, and No 32 wire painted black. Ordinary window-screen cloth is of the same size of wire, and 12 to 14 meshes to the inch. This special cloth is, therefore, more transparent, and obstructs the vision less, than any other cloth we were ever able to secure. One objection to a veil of this kind is its bulk and the difficulty of transporting it, either by mail or when packed with other goods. We have overcome this one objection by

making it with an open seam from the crown to the bottom of the skirt. Eight small safety-pins are included to pin up this seam when you receive it, or you may prefer to sew it up. The veil is rolled up so as to be placed in a box 3 x 3 x 12 inches so that it can be mailed safely for 12 cents postage, or packed with other goods to go by freight. Price, complete, 60 cts. By mail, 72 cts. Special wire cloth for veil furnished at 6 cts. per foot or piece for a veil at 18 cts., by mail, 3 cts. a foot extra, or 25 cts. postpaid for a veil-piece 10 x 33 inches, having edges folded ready to sew on the cloth parts.

SIMPLEX HONEY-JARS.

The factory have assured us that we may again secure this popular honey-jar in several sizes, including the one holding one pound of honey. We have ordered a fresh supply, and expect to have them in stock this next month. They will be packed in reshipping-cases of two dozen each, and the price will be \$1.10 per case; 6 cases, \$6.30.

NO. 25 HONEY-JARS.

During the past year we have had an unusual amount of trouble with breakage of this jar, even in the reshipping-cases packed with corrugated paper. The breakage occurred either in the porcelain cap or the top rim of the jar where the cap rests. We find we can get this same jar with lacquered tin cap without the center being cut out. This cap is lined with waxed paper wad, which seals tight on the top edge of the jar. This style of cap not only does away with breakage almost entirely, but enables us to furnish the jar at a lower price. We are not yet supplied with the new stock, but expect to have them this month at the following price. They will be packed as usual, two dozen in reshipping partitioned cases. No. 25 jars, tin cap lined, 90 cts. per case; 6 cases, \$5.10. We can still furnish from stock the usual style of No. 25 with porcelain caps at \$1.10 per case; 6 cases, \$6.30.

A NEW SIZE OF SECTION.

There seems to be a demand in some localities, where bees are inclined to daub with propolis or otherwise discolor the wood in sections for a wide frame completely enclosing the sections. Our regular supers are adapted to the regular sections in section-holders without a top-bar. To provide a top-bar as well as a bottom it is necessary either to make the super deeper or the section shorter. In order to use the regular deep super we have decided to make a new section, 4¼x4¼x1½ or 1½ plain, no beeway. This will be used in a section frame hanging by top-bar in the regular deep super, interchangeable with the shallow Hoffman frame 5¾ deep. This will necessitate a new fence adapted to this size of section, which will be designated by the letter N. The 4¼x4¼x1½ will hold a full pound, and will work best in the eight-frame super, 24 to the super. In the Danz, width (16¼) ten-frame super the 4¼x4¼x1½ will fit best 32 to the super. These sections may be split for inserting foundation by the Hand method, and the correct size of sheet for that purpose would be 4¼x17¼. Price of N section-frames, \$2.50 per 100 in flat. Price of N fences, \$2.00 per 100. Sections 4¼x4¼x1½ or 1½, same price as regular Danz., \$4.75 per 1000, No. 1; \$4.25 for No. 2. Unless you specify we will send frames and sections 1½ wide, and supers fitted with the same. Deep super fitted with N section-frames,

N fences and springs, either 8 or 10 frame, will be designated 2 N 8. Price, nailed and painted, 70 cts. each; in flat, 55 cts.; 5 for \$2.50.

2 N 10. Price, nailed and painted, 75 cts. each; in flat, 60 cts.; 5 for \$2.75.

With sections and foundation-starters included.

4 N 8. Price, each, nailed and painted, \$1.00; in flat, 75 cts. each; 5 for \$3.50.

4 N 10. Price, each, nailed and painted, \$1.05; in flat, 80 cts. each; 5 for \$3.75.

With sections and full sheets of foundation.

1 N 8. Price, each, nailed and painted, \$1.40; in flat, \$1.00 each; 5 for \$4.50.

1 N 10. Price, each, nailed and painted, \$1.45; in flat, \$1.05 each; 5 for \$4.75.

These are not listed in our catalog this season, and not in stock with any of our dealers. If you wish to test them you will have to make special orders to secure them. You can get them through your dealer if you order in ample time and are not in a hurry to receive them. This section will require a new size of carton and a new size of shipping-case to put them up for market. We offer the new size for experiment this season to see if it has sufficient warrant for introduction into the top and bottom they could be stored without fences or separators, and four could be placed in a shallow Hoffman frame for storing, though they would not be as well protected as in a section-frame. The latest style of shallow frame with 4-inch ends would be rather scant in length inside to take four sections, but those made earlier would have room.

Convention Notices.

The Central Tennessee Bee-keepers' Association will meet in the rooms of the Nashville Board of Trade on Saturday, April 25, at 10 A.M. A full attendance of the members is desired, as this is the regular annual meeting for the election of officers, etc. A good program has been arranged, which will include essays and discussions on subjects of interest to bee-keepers.

J. M. BUCHANAN, Sec.

Franklin, Tenn.

The seventeenth annual convention of the Connecticut Bee-keepers' Association will be held in Jewell Hall, Y. M. C. A. building, Hartford at 10:30 A.M. Apr. 9, for the election of officers and the transaction of any other business proper to come before the meeting. A program of unusual interest and value is being arranged and no bee-keepers should fail to attend. The matter of organizing a fall fair, under the provisions of a State law, is to be considered, which will be of vital interest to the honey industry.

J. A. SMITH, Sec.

The Northern Michigan Bee-keepers' Association will meet in convention at Mancelona, April 8 and 9. There will be three sessions on Wednesday, the 8th, and two on Thursday. The headquarters will be at the Handy Hotel, and the place of meeting, Medalie Hall. Ladies are cordially invited, especially for the last day, when a picnic dinner will be held at the hotel.

PRIZES.

Best case comb honey.—1. One Danzenbaker hive, nailed and painted. A. I. Root Co. 2. American Bee Journal one year.

AT SPRINGFIELD, MASS.

New Goods. Free Catalog. Phone.

F. R. DANIELS, 117 FLORENCE ST.

Mr. Bee-keeper, ☐

Was 1907 a POOR YEAR for you?

It was a GOOD YEAR for users of

DADANTS' FOUNDATION.

One dealer used 14,000 pounds.

Another dealer used 7,250 pounds. Another dealer used 4,500 pounds. Another dealer used 4,500 pounds. Another dealer used 3,000 pounds.

Thousands of pounds sold to the bee-keeper direct, or worked up for him out of his beeswax.

The DEALER likes DADANT'S FOUNDATION because the bee-keeper likes it.

The bee-keeper likes it because his BEES like it.

The BEES like it because it is exactly like their own comb, so PURE and SWEET and CLEAN.

DADANT'S FOUNDATION is the Standard because it is the BEST.

Wax worked into foundation.

JAMESTOWN, N. Y.

WE ARE GROWING

Because the Root Brooder

IS

The BROODER THAT BROODS

and the Poultrymen are Quick to See its Good Points.

It's the only one that gets away from that old-fashioned hot-air hover.

It's the only one that supplies the warmth to the chicks as the old hen does it

The chicks come in contact with these warm tubes and breathe cool, fresh air at same time.

Read
"Our Homes"
by

A. I. Root,
March 1st
issue.

This picture shows how easily the heater and lamp are removed. The chick floor below the tubes can be taken out for cleaning without removing the heater.

Mr. Chester H. Cook, of Wallingford, Conn., writes: "In regard to the Root Brooder which I bought of you last spring would say that I am well pleased with it. I find it superior in every respect to all other Brooders that I have run or seen used, of which I have some of the most popular makes. I have taken chickens with leg weakness from my hot-air brooders and put them in the Root, and within a day or two they were lively as crickets. No more foul hot-air brooders for me. Wishing you the best of success in the future with your machines. P. S. The last brooder I ordered from you arrived a few days ago and I must say they are put up in fine shape.

Mr. A. J. Bartlett, of Vineland, N. J., reports, "Our results with the Root Brooders are very flattering; for instance, in our last two hatches (Feb. 15, 1908) we raised 100 per cent of chicks hatched.

The Root Brooders are so constructed that the chicks can not pile one upon another. Our 1908 catalog gives an accurate and thorough description of the Root Brooders, and will be sent to you upon request.

Cleanings in Bee Culture

Apiary of circular hives covered with straw in the Caucasus Mountains, Southeastern Russia.

Published by The A. I. Root Co., Medina, Ohio, U. S. A.

Entered at the Postoffice, Medina, Ohio, as Second-class Matter.

Our Comb-honey Outfit No. 6.

It is always a matter of considerable difficulty for the average beginner to decide exactly what he requires as an outfit for the first effort in keeping bees. To relieve the beginner of all perplexity we list certain outfits which we think will meet his needs. The one we give below is what may be fairly considered the best. Each item has been very carefully selected and we doubt the wisdom of leaving any article out; but the purchaser may do so without altering the prices on the other items.

A B C and X Y Z of Bee Culture . . . \$ 1.25

A year's subscription to "Gleanings in Bee Culture" 1.00

(A large illustrated semi-monthly magazine.)

A Junior Root Smoker65

A pair cotton bee-gloves (small, medium, or large) .35

Bee-veil No. 2, with silk front60

One full colony Italian bees in Danzenbaker hive 11.00

(Complete with 32 section honey-boxes.)

A tested Italian queen 2.50

Two Danzenbaker hives complete for comb honey 6.20

(Nailed and painted, ready for the bees.)

\$23.55

Some may regard this as too expensive an outfit; but it should be borne in mind that the colony of bees is just about perfect. The comb, for example, are beautifully straight and nearly full of brood. The breeding of the queen is of the very best, so that one has the nucleus of a fine stock of bees. In many cases a return of \$10.00 in honey has been secured the first year from just such an outfit as this, and in addition one swarm and possibly two may be secured, which practically doubles the value of the investment. This is not an uncommon occurrence. On the contrary, scores of men have done as well or better, where the conditions were at all favorable.

Providing any one has a liking for bees, we would earnestly urge the propriety of securing one of these outfits this spring. One is never too old to learn bee-keeping, and there is no more delightful out-door vocation. It is just right for busy folks who must have a hobby. In fact, there can be nothing better.

If this offer is not quite to your liking, write us. We answer questions. To show we are not exaggerating the profits of bee-keeping when conditions are favorable, we insert the following unsolicited testimonial from a man of unquestioned integrity. We could secure many more like this if we chose to ask for them.

ST. PETER'S LUTHERAN CHURCH, NEW YORK, March 11, 1908.
The A. I. Root Company, Dear Sirs:—Enclosed please find my check for payment of my subscription in arrears for five years. I greatly appreciate GLEANINGS, not only for the good and plain reading matter, but also because it furnishes many kinks, which otherwise one would be unable to find out. These kinks have enabled me in the last three years to sell from ten colonies on the average over \$100.00 per year. I donate the honey to my church for charitable purposes, and the members are eager to buy, because they know my honey is absolutely pure.
Yours very truly, DR. A. B. MOLDENKE.

The A. I. Root Co., Medina, Ohio.

**OUR
GRAND 1908
OFFER**

**NEW
LUMBER**

**FIFTY MILLION FEET
AT REDUCED
PRICES**

Bought at Forced Sales from Manufacturers. It makes us Headquarters for Thousands of Genuine Bargains in Lumber and Building Supplies. We save you money.

**BIG
SPECIAL
SALE**

SAVE 30 TO 60 PER CENT. BUY DIRECT. BUILDING SUPPLIES OF EVERY KIND

The Chicago House Wrecking Co. Purchased at forced sales, \$0,000,000 feet of new lumber. We are making special concessions to those who buy at once. Our prices today are far lower than prices have been for years. Order now for immediate or future use. Quick action will save you big profits. Remember prices elsewhere which are even now high, are bound to rise. We can quote you 30 to 60 per cent better prices for the same lumber than your local dealer. We guarantee every carload to be exactly as represented. Closest inspection of our lumber stock invited.

Call at our warehouse and yards at Chicago and see the lumber we are offering and you will recognize that it is all we say of it. Make your own selection and see it loaded. It is not necessary to come to Chicago, however, unless you wish to. We can fill your order by mail with just what you want and guarantee you absolute satisfaction. Ours is the largest direct to the

consumer lumber headquarters in the world. We sell millions of feet annually. Orders filled from every part of the United States. No matter where you live you can save money by supplying your building wants here.

We do not figure fancy prices, but quote figures that command your patronage. Whether your order is large or small we can save you money on it. Our tremendous business of millions of dollars annually is your best guarantee of complete satisfaction of every purchase made from us. In our enormous stock of new lumber of every kind we have just what you need for every purpose. Don't buy a stick of material until you get our prices. We offer you everything in the lumber and building supply line needed for residences, farm homes, stores, churches, barns, outbuildings of every kind, sidewalks and fencing. In short any kind of a structure requiring lumber, at from 30 to 60 per cent less than your local dealers or lumber yards ask for it.

IMPORTANT! Send Us Your Lumber Bill For Our Estimate

Make up a list of what you need. Send it to us for our price. If you are putting up a building of any kind whatsoever let us figure with you. Our prices talk louder than words. Have your carpenter or contractor send us your list of what is needed if he has charge of your building. Don't pay exorbitant prices to the lumber trust with their long line of lumber yards all over the country. Don't let the local dealer soak you with his heavy profit. Remember: Chicago House Wrecking Company buys millions of feet at a time under circumstances of forced sales which means sacrificed prices and enables us to sell even as low as cost without loss. You take no chances in dealing with the Chicago House Wrecking Company. Whether for \$1 or \$10,000 your order will be filled carefully. Our lumber and supplies are guaranteed exactly as represented. If you have no need for a whole carload yourself get your neighbors to club in with you. By buying a carload you can save all kinds of money on freight charges.

We have railroad trains running through our main warehouses and buildings and can load a car to good advantage to you. You can include in this same car, pipe, plumbing material, roofing, wire, fencing, furniture, hardware and merchandise of every kind.

We also furnish you building and barn plans absolutely free upon request. Write us for any information or advice you want and we will have our staff of architects answer every inquiry promptly. Our free book of plans is sent if you mention this paper. We simplify your building proposition.

Our business demands quick action. We must keep our stocks moving. This means prompt shipment—no annoying delays. Let us help you lay out your plans. We will relieve you of every detail. That is what our Special Builder Service is for. Be sure and send us your lumber bill for our estimate. Feel free to write for anything you want to know along the line of building supplies, furnishings, etc.

WE PURCHASE OUR GOODS AT Sheriffs' and Receivers' Sales

Chicago House Wrecking Co., Chicago

Honey Markets.

GRADING RULES FOR COMB HONEY.

FANCY.—All sections well filled, combs straight, firmly attached to all four sides, the combs unsoiled by travel-stain or otherwise; all the cells sealed except an occasional one, the outside surface of the wood well scraped of propolis.

A No. 1.—All sections well filled except the row of cells next to the wood; combs straight; one-eighth part of comb surface soiled, or the entire surface slightly soiled; the outside surface of the wood well scraped of propolis.

No. 1.—All sections well filled except the row of cells next to the wood; combs comparatively even; one-eighth part of comb surface soiled, or the entire surface slightly soiled.

No. 2.—Three-fourths of the total surface must be filled and sealed.

No. 3.—Must weigh at least half as much as a full-weight section.

In addition to this the honey is to be classified according to color, using the terms white, amber, and dark; that is, there will be "Fancy White," "No. 1 Dark," etc.

The prices listed below are intended to represent, as nearly as possible, the average market prices at which honey and beeswax are selling at the time of the report in the city mentioned. Unless otherwise stated, this is the price at which sales are being made by commission merchants or by producers direct, to the retail merchant. When sales are made by commission merchants, the usual commission (from five to ten per cent) cartage, and freight will be deducted, and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage, and other charges, are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

PHILADELPHIA.—The sale of both comb and extracted honey has been very light ever since the holidays until last week when the stock in the stores was cleaned out somewhat, and there has been quite a demand for comb honey. Prices, however, seem weak, and large lots are being offered through the commission men from bee-keepers who have been holding their honey back for better prices. We quote: Fancy comb honey, 15 to 16; No. 1, 14 to 15; amber, 12; extracted, fancy white, in 60-lb. cans, 8½ to 9½; light amber, 7 to 8. Beeswax, 28. We do not handle honey on commission.

W. M. A. SELSER,

March 30. 10 Vine St., Philadelphia.

BUFFALO.—The honey market here is very dull. Receipts of white-clover comb honey are liberal. Buckwheat is cleaned up. Prospects are rather discouraging for the rest of the season. No. 1 to fancy white comb honey, 15 to 16; No. 2, 12 to 13; No. 1 buckwheat, 11 to 12; No. 2 buckwheat, 9 to 10; white-clover extracted, 9 to 10; amber extracted, 7½ to 8; dark extracted, 7 to 8; tumblers, per dozen, 90 to \$1.00. Beeswax, 30 to 32.

W. C. TOWNSEND,

March 27. Buffalo, N. Y.

CHICAGO.—The market is without any life. A little honey is being taken as the retailer exhausts his stock, but no lots are moving. Prices are about as last given in comb. Extracted is lower, especially the western product. Beeswax is wanted at 30 when clean and yellow.

R. A. BURNETT & Co.,

April 8. Chicago, Ill.

DENVER.—The market on comb honey is slow, and prices are declining. We quote to our trade, No. 1 white, per case of 24 sections, \$3.00; No. 1 light amber, \$2.85; No. 2, \$2.70; extracted, white, 8 to 9; light amber, strained, 6¾ to 7½. We pay 25 cts. for clean yellow beeswax delivered here.

THE COLORADO HONEY-PRODUCERS' ASS'N,

March 31. F. Rauchfuss, Mgr., Denver.

INDIANAPOLIS.—Jobbers are fairly well stocked, but very little honey is being offered by producers. Best grade of extracted honey is in good demand, but comb honey is finding slow sale. Jobbers are offering the following prices, delivered here: No. 1 and fancy comb, 15 to 17; extracted white clover, 8 to 9; amber, in barrels, 6 to 6½. Beeswax, 28 cts. cash or 30 in exchange for merchandise.

W. S. POWDER,

April 3. Indianapolis, Ind.

SAN FRANCISCO.—There is no movement to speak of in honey, as stocks are quite small, with little coming in, and the prices tend to limit the demand. We quote: Water-white, comb, 16 to 17; white, 15; water-white, extracted, 8 to 8½; light amber, extracted, 7 to 7½; dark amber and candied, 5¼ to 5½.

Pacific Rural Press, March 28.

CINCINNATI.—The market on comb honey is very quiet. There is no demand. Water-white sage honey is selling at 9 to 10; amber, in barrels, 6 to 6½. Beeswax is in fair demand, selling at 32.

C. H. W. WEBER,
Cincinnati, O.

March 30.

HAMBURG.—Prices of honey are as follows: California, 8½; Chile, 4½; Cuba, 4½; San Domingo, 4½; Mexico, 4½. Beeswax, Benguela, 30; Brazil, 32; Cuba, 30; Chile, 31; Madagascar, 29; Morocco, 30; Carnauba, yellow, 34; ditto gray, 28.—*L'Apiculture Nouvelle*.

BARCELONA.—Spanish beeswax, 29 to 31; foreign, 30 to 31. Extracted honey, first class, 5½; second class, 5½; strained honey, 5; foreign honeys, 10; foreign, second-class, 8 to 9.—*L'Apiculture Nouvelle*.

NEW YORK.

The Hive that Makes Good= Because It Is Made Right!

MUTH SPECIAL

Is honestly the very best and most practical hive on the market to-day.

We offer it as a *leader*, because it *is* one! Regular Dovetailed hive, but finished like a parlor car—finest cover and bottom you ever saw.

Cover is gable-style, and can't blow off; has rim rabbeted on the inside edge of the sides, so it has to stick to its job. A honey-board (with the aid of a Porter bee-escape, enabling you to take off honey without a sting) is furnished with each hive.

Bottom is reversible, and it simply *can't* warp.

Look at the construction of this hive, as shown in the above photograph, and then tell us if you ever saw a better.

Here are prices:

WE'VE MOVED

TO
LANSING, MICH.

WE NOW HAVE

Larger Quarters.

A large warehouse has been secured, enabling us to store large quantities of goods for prompt shipment.

Better Facilities.

We are located close to the depots, insuring quick deliveries to the transportation companies.

More Railroads.

Grand Trunk, Lake Shore, Michigan Central, Pere Marquette—the four leading railroad systems of Michigan, reaching all sections of Lower Peninsula with better service than any other four roads.

More Express Offices.

American, United States, National.

All these advantages are for the purpose of enabling us to attend better to the wants of the bee-keepers of Michigan and surrounding territory.

Headquarters for "Root Quality" Bee-supplies

We make it our business to please bee-keepers in search of the right bee-supplies. If you have time to come and see us in our new establishment we shall be glad to see you. All bee-keepers welcome. Make our store your headquarters while in Lansing. Send for our catalog. Root's factory prices.

CARRIAGES AND BUGGIES.

If you are on the outlook for a family carriage or buggy we should like to call attention to the advertisement on page 451 of the Elkhart Carriage and Harness Manufacturing Co., Elkhart, Ind. This is one of the largest firms, if not the largest, of the kind in the world. They have been dealing direct with the public, without the intervention of the middleman, for a period of 35 years. In fact, we think they were pioneers in the business of selling vehicles by mail. They have built up an immense business by fair and honorable dealing, without which a mail order business could not long exist. Our older readers do not need an introduction, because the firm is well known to them by its advertisement in these columns year after year, and many of them purchased their family conveyance from this source long ago when ordering by mail was something new, and a daring thing to do. The catalog of the firm is always to be had merely for the asking; and as it lists over 200 vehicles and 65 styles of harness it is really worth sending for. If you send for it, please mention this journal.

THE CHARM OF EVERGREENS.

There is a place on every farm for evergreen trees. A thick belt of high evergreens makes a splendid shelter from wintry blasts. Protection of this kind is very welcome to the cattle, sheep, and poultry on a farm, more particularly when the trees are so planted as to check some peculiarly trying wind which blows in springtime when animals want to get out of doors after a long winter's imprisonment. Then, too, these trees serve to embellish a place and screen more sensitive plants and shrubs. Splendid hedges may be made of Norway spruce and arbor vitae. A thicket of pines or firs is an excellent roosting-place for the turkeys, guineas, and pheasants; and the chickens also appreciate it. Many evergreens are decidedly ornamental, such as the blue spruce, the cedars, and the junipers. We are moved to make these remarks by perusing the catalog of Mr. D. Hill, box 87, Dundee, Ill., who is a prominent specialist in this line. He has made a study of evergreens for the prairie States, and has been very successful in finding them.

SAVING

is more important than hard work.

Money deposited with us is secure and works for you continually. Our perfect system of Banking BY MAIL brings this opportunity to your door.

**"If goods are wanted quick, send to Pouder."
Established 1889.**

Outlook Is Cheerful.

By the Bee Crank.

Said a great evangelical preacher,
"The hen is a beautiful creature,"
And the hen, just for that,
Laid an egg in his hat,
And thus did the Hen-reward-
Beecher.

A Florida hen cackled and thus
betrayed
That a fine large egg she had just
laid.

And a bee-man of fame
Was heard to exclaim,
"Oh beautiful thing! come under
my wing;

It's us for the land where the
mockingbirds sing.
—And if a 'jigger' bites me, I'll
forget it."

a complete stock on hand. My illustrated catalog is free, and I should like to send it to you, and should be pleased to quote an estimate on your wants; or if in a hurry you can order from the Root catalog, my prices being identical with factory list. This man sent for an estimate, and then

wrote as follows:

Walter S. Pouder. CONNERSVILLE, IND.

Dear Sir:—Your favor with estimate received. When freights are taken into consideration your prices are the lowest; and when I buy Root's goods I know what I shall get, which is worth something to me. Inclosed you will find check with order, and I am sending my beeswax by express.

Yours, THOS. H. WHITE.

Beeswax Wanted: — Don't waste beeswax, but save it and send it here. I pay highest market price, cash or trade, and I have an outlet for every pound that I could secure, and could use more.

Whether the story is true or not, there seems to be some circumstantial evidence to support it. Meanwhile I am making a specialty of selling Root's goods at Root's prices, and have a very complete stock of new goods. The indications are that, during May and June, the demand will be tremendous, and I am prepared for such an event. I could ship a ton of foundation the day the order reaches me, and still have

Walter S. Pouder,

513-515 Massachusetts Avenue, Indianapolis, Ind.

Bees For Sale.

My bees have wintered perfectly—clean, dry, and free from dysentery—and I have decided to sell a few colonies. The bees are of the Superior stock, the hives nearly new, in good condition, and well painted. The combs are all-worker—mostly built on wired foundation. Everything is strictly first class.

For a colony in an eight-frame Langstroth hive the price is \$6.00; in a ten-frame Langstroth, or in a new Heddon hive (two sections) the price is \$7.00; and to each purchaser of one or more colonies the Review will be sent free for 1908.

I am now ready to accept and book orders accompanied by the cash; and when I have received as many

orders as I care to fill, no more will be accepted. The bees will be shipped by express, about the close of fruit-bloom, when the newly gathered honey will furnish the necessary water, and safe arrival will be guaranteed in every respect.

If you wish to stock your apiary with a strain of bees that has no superior, here is a chance to get a breeding-queen, such as the most of dealers ask from \$3.00 to \$5.00 for, already introduced, in a full colony, whereby she can be shipped without injury, early in the season, all at a moderate price.

W. Z. HUTCHINSON, Flint, Mich.

BEE KEEPING

will be a profitable industry this season.

Honey is high—short crop last year. The shortage of the honey crop for 1907 in the United States warrants bee-keepers to increase their colonies. About a half crop was produced, and in California, where the cheap honey comes from, only a quarter of the average crop was produced.

Get Ready Now for More Honey

Let us send you our catalog. We are manufacturers and sell only our own make of bee-supplies. Minneapolis is the largest lumber-distributing point; the Mississippi river furnishes us power, and our organization and labor conditions are the best for economical production. Send us an estimate of your requirements and let us give you prices. We have a large stock of standard bee-supplies on hand.

TO THE BEE - KEEPERS OF CANADA.

WE are pleased to say that we are able to offer, in Canada, goods manufactured by The A. I. Root Co. While we do not offer every thing listed in their catalog, we have selected such articles as we believe will best meet the wants of the Canadian bee-keepers.

The heavy duty and freight charges we have to pay make it impossible for us to sell in Canada at Root's prices. We have, however, made prices as low as possible, and in no case do we charge nearly as much extra as the amount of freight and duty we ourselves have to pay on the goods.

We would ask you, when comparing our prices with those of other dealers, to take into consideration the QUALITY. If you do so we feel satisfied that you will place your order with us. The splendid quality of the material sent out by The A. I. Root Co. has given "Root's Goods" a world-wide reputation. Remember, The best is cheapest."

Jamestown Exposition, 1907

IS THE BEST,
STRONGEST,
COOLEST,
CLEANEST,
CHEAPEST,
AND LARGEST
SMOKER SOLD
FOR A DOLLAR

The perforated side grate seen above holds a removable, metal, asbestos-backed fire shell, preventing burning the tin off the outer case, and deflects the air at right angles, preventing back draft to the valveless bellows. The air, passing to the back and over the top, cools and expels the smoke, fanning the burning fuel at top or side till all consumed, giving cool smoke for hours from one filling. It can't clog. No top-heavy cap to choke with soot: no valve to fail; no holes shedding sparks or hot ashes.

Four years' sales prove its success beyond a doubt, expensive dies making it uniformly perfect as possible to devise. We confidently guarantee full satisfaction or refund the price.

Price, \$1.00; 3 for \$2.50; by mail, add 25c. each

Send address of yourself and Bee friends for 8-page leaflet on "Smoker," and facts about Bees and Queens, 80 pages, free.

BEE SUPPLIES

**Distributor of Root's Goods
Exclusively, at Root's
Factory Prices**

GIVE ME YOUR ORDERS for the **Best Goods Made**. You will be pleased on receipt of them. You will **save money** by ordering from me. My stock is complete; in fact, I keep **every thing** the bee-keeper needs. Cincinnati is one of the best **shipping-points** in the Union, particularly in the South, as all freight now **goes through Cincinnati**. Satisfaction guaranteed. Send for descriptive catalog and price list. It will be mailed you promptly **free of charge**.

Special Discount on Early Orders

I will buy your **HONEY AND BEESWAX**. I pay **Cash on Delivery**; or if you are in **need of honey**, write for prices and state quantity wanted, and I will quote you the lowest price of any quantity wanted—in cans, barrel-lots, or car-lots—of **extracted** or **comb honey**. I guarantee its purity.

WANTED=Sweet Clover.

If you have **Sweet Clover**, state if yellow or white, hulled or unhulled, also quantity and lowest price.

No. 8

J. E. HAND, page 422, evidently thinks the best time for spring feeding is in the fall. Here's my hand on that, friend Hand.

ILLINOIS failed to get county option, but our new township-option law is making things lively for the saloons. Now that you Ohio fellows have county option, you ought to make things just hum.

PHILIP B. STEWART, I don't believe you will like any of the plans you propose, page 445, unless it be the plan with box hives. Most, however, would prefer the plan given by W. K. M., only by some mistake he is made to say that the bees should be driven out 15 days after swarming. It should be 21.

F. DANZENBAKER thinks I should put nothing in the two-inch space under frames to prevent bees building down, p. 447. Worth thinking over. But when the bees fill up the space with comb, will it not be the same as if there had been in the first place deeper combs with no deep space? Besides, the combs are generally built crosswise, making bad work lifting out the frames.

WHAT CAN possibly make such a difference between F. Greiner's experience and mine? He says, p. 435, that in the few cases when he left nothing but a board cover over his supers, with the hot sun upon them, the result was the loss of a super of honey. I do not think I ever had a section injured, to say nothing of the loss of a super, and I've had hundreds and hundreds of cases of the hot sun shining upon an unpainted single-board cover on the super. I wonder if his hives are in too close surroundings. I once had combs melt down in a hive in shade so dense that the sun never touched it, but with undergrowth on all sides to hinder free circula-

tion of air. [The difference may be accounted for on the basis of locality as well as the immediate surroundings.—ED.]

DYSENTERY is mentioned, p. 418. Better call it diarrhea. Even that is a pretty strong term if there is nothing more than overloading the intestines. [We have known for some time that the word "dysentery" was not the correct or technical one to describe a certain disease of the bees in spring, and that "diarrhea" was much more exact; but, unfortunately, the former term has become so thoroughly incorporated in our literature and the minds of our correspondents that it has come to be one of those words that we can not very well change.—ED.]

REPLYING, Mr. Editor, to your query, page 411, I do not believe that ventilation at each story "requires a large portion of fielders to stay at home to keep up the necessary body heat." The nurse bees are sufficient for that at any time when a flow is on, and are not even they sometimes forced to hang out idle when ventilation is insufficient? [Are you sure that there will be enough nurse bees in all localities to keep up the necessary body heat in double or triple deckers when you storify or pile one super on top of another in such a way as to leave ventilating-gaps? If there has been a large amount of brood-rearing at the right time, it is conceivable that there might be enough of such young bees.—ED.]

TAKING AWAY combs from a ten-frame hive and filling out with dummies when the harvest commences, as recommended on p. 417, has the disadvantage that sections over the dummy or dummies at the side will be slowly worked. A limited experience, however, leads me to believe that this may be remedied by putting the dummies, not at the side, but between the combs, one in a place. Contrary to my expectation this did not seem to hinder the work of either bees or queen. [A good suggestion. If a dummy be put in the center of the brood-nest it will have a tendency to force comb-building in supers clear out to the sides, and still the center will not be neglected.—ED.]

I REFUSE to be convinced, Mr. Editor, that when I say it does not pay me to paint my hives I am thereby arguing that hives will not last longer, and look nicer if painted, p. 412. As to the rest, you are quite right in stating my position as far as you go, but not right as to Mr. Doolittle. He believes unpainted hives are better for the bees, and I suspect he is right. You say I have changed hives once already in forty years. Worse than that. In forty-seven years I have changed five times—from a sugar-barrel to Quinby box hives; then to the Lester frame hive; then to the Vandervort with frames 18 by 9; then to the Langstroth; then from ten frame to eight frame; also changing from several kinds of frames to the Miller frame.

CAN YOU TELL, Mr. Editor, when Neponset-covered covers came into use? You sent me one of the first, I think, with instructions to paint. I didn't paint, but the cover seems just as good yet. [We introduced it some five or six years ago, and at that time a correspondent, in calling our attention to it, stated that he had covers covered with the paper that had been used for twelve years, and it was then as good as ever. We have covered a large number of our hives with the material, and find it to be very durable, either with or without paint. We feel satisfied that it will outlast the ordinary *steel* tin plate. The only objection to it is that it will not stand much rough handling, such as piling a heavy hive on top of it in such a way as to gouge into the paper.—Ed.]

THE METHOD of using two starters in sections, one at top and one at bottom, "still leaves a chance for pop-holes and bee-spaces in the comb at the sides," page 433. I don't wonder at your thinking so, Mr. Editor; but if you were to see a crop of my honey I think you would decide the bees had not made good use of their chance for pop-holes. Look at "Forty Years Among the Bees," pp. 283, 285. Of course, the sections there pictured were selected as the very best, and yet hundreds of others were like them. But look at pages 15, 269, 271, 279. Those sections were taken with no thought of avoiding pop-holes, many of them being unfinished, and not filled out as they would be later. [Your evidence, doctor, seems to be quite conclusive. Apparently you had already put into practice, in part at least, our suggestion as given on page 433, April 1st issue. If so, it would appear that comb honey without pop-holes *can* be produced by a large top starter reaching almost to the bottom, and a narrow bottom starter, providing both starters nearly touch the wood on either side. This allows for the sagging of the foundation and a slight side stretch. Of course, you keep your sections square; for foundation cut nearly to a fit (in width) requires square sections and square cutting—at least the top sheet.—Ed.]

ALLEN LATHAM asks, "Had you ever thought that it stands to reason that there should be a poor joint between top starter and bottom in sections?" I must confess that it does, after his calling my attention to

some points. Only rarely will top and bottom starters exactly correspond so as to be the same as a continuous sheet of foundation, and the top starter will not always be in exact alignment with the bottom. I confess I had been so well satisfied with the finished product that I had never critically examined the work of the bees at that point; but happening to have on hand five sections emptied of honey by the bees, I have just made such examination. In the first four there was nothing to show that the foundation was not continuous from top to bottom. In the fifth case there were plainly three cells out of shape and unusually large. That was all that showed on the surface; but looking into the cells, and especially after cutting in, it was easy to see that the top was about $\frac{1}{2}$ inch out of alignment with the bottom, the bees having built horizontally across from one starter to the other. But in sealed sections there is no indication that the section was not entirely filled with a single starter. Just how the bees manage it, or why they don't do the crooked work that reason ought to expect, is beyond me. I only know that, when the section is done, it's all right.

YOU ARGUE, Mr. Editor, page 412, that by taking away from a weak colony a comb just as soon as the queen has filled it, and replacing it with a comb of just-hatching brood, you can get the queen to lay in a smaller room as many eggs as a queen having a strong force of bees. Let us see. Suppose A is a strong colony and B a weak one. You take from B a frame of eggs and young brood and exchange with A for a frame of bees just emerging. There will be a big gain in B because there isn't the waiting for empty cells there would have been without the change. But you forgot about A, didn't you? Don't you see that A will have to do exactly the same waiting that you have saved B from, and that you have just hindered the queen in A by so much in *her* laying? [If you will turn to page 412 you will notice that we specify that, in order to get an equalization of queen-laying on the Hershiser plan, there would have to be a "proper coöperation on the part of the apiarist." In the case you cite between colonies A and B, it is apparent that, with no further manipulation, queen A would not be able to lay to her full capacity. But what is to interfere with the apiarist giving A an empty comb at the time he gives her a frame of young brood from B? If he does this, both queens might lay at pretty nearly an equal rate. This would be a case of proper coöperation on the part of the apiarist. It is true that it would take one extra comb. But in that case, of course storifying might be necessary. When we use the term "storifying we are using the excellent English word for "tiering up" one story on top of another. But suppose colony A does not need young brood, or, for that matter, the empty comb for the queen to lay in? It is possible that, by letting a queen lay to her full capacity, the strong colony might, as E. D. Townsend says, p. 419, be ahead of time for the harvest.—Ed.]

SECRETARY W. Z. HUTCHINSON is doing some good work on plans for the next National convention at Detroit. See Convention Notices on page 525.

HOW THE BEES ARE WINTERING.

REPORTS from nearly every portion of the United States seem to indicate splendid wintering; in fact, we may say that in all of our experience we do not remember the time when bees came through so well.

HONEY CROP PROSPECTS FOR 1908.

WE have just gone over a large number of reports that have accumulated within the last few days. The prospects for a good honey crop are favorable.

For the North the winter has been mild, and spring not so early as to start brood-rearing out of season to be chilled later on.

Reports from California are somewhat conflicting. Early in the spring bountiful rains had come, seeming to insure a good honey crop; but since that time conditions have been less favorable in some sections. As it is, we judge there will be from a light to a fair crop; and should the situation change for the better, the crop may be a good one.

Conditions are exceedingly good for a flow in Texas. It begins to look as if the Lone Star State would redeem its reputation. Its bee-keepers could once boast of a certain crop year after year; but during the last two years it has been a failure in many sections.

Reports from other portions of the South are favorable. It is too early to predict any results in the central and northern States.

SPRING OR FALL FEEDING; FURTHER REPORTS.

IN answer to our request, as given on page 337, March 15th issue, for brief reports, quite a sprinkling of responses have come in. The consensus of opinion summarized is about as follows:

1. Don't feed in the spring.
2. Give combs of sealed stores to hives short of stores.
3. If these are not available, and colonies are likely to starve, give liquid syrup; or better
4. Feed the strong colonies, and give their sealed combs to the weak ones short of stores. We consider this suggestion excellent.

To stimulate brood-rearing in the spring it is advised to scratch the surface of the sealed combs of honey next to the brood rather than to feed thin syrup. This is also good.

WHAT AN AUTHORITY ON AGRICULTURE HAS TO SAY OF ALSIKE.

It is seldom that we read any thing more to the point than which Mr. Alva Agee has to say of alsike, in *The National Stockman and Farmer*, as a forage-plant for farmers. He certainly can not be accused of booming the plant in order to help the bees. In answer to a correspondent he says:

Alsike clover is sown with wheat or rye, or is seeded alone, like medium red clover. The seeds are about half as large as those of red clover, and therefore half the quantity per acre is sufficient. However, I doubt whether you want to seed to alsike unmixed, as it inclines to lie close to the ground, having more of the creeping habit than the common red. Moreover, its roots do not penetrate the soil as deeply as is desirable in a fertilizing plant. These are its two weak points. On the other hand, it is surer to make a stand than the red; it lasts longer in pasture and meadow, and it ripens more nearly with timothy. For many years our paper has urged the mixing of alsike with medium red for all land inclined to be unfriendly to clover. Alsike is pretty sure and dependable on any kind of land; and especially is it superior to the red on wet land. It makes a fine hay, but it yields less than the medium red. For pasture it is our most valuable clover.

ALVA AGEE.

Bee-keepers would do well to help spread the doctrine among the farmers. They should get their local papers to publish it. It is good stuff.

DR. WILEY STILL HAMMERING.

IN spite of the adverse glucose decision, Dr. Wiley is still on deck losing no opportunity to hammer the adulterators. At the International Congress of Mothers he had this to say, which we clip from the *American Grocer*:

"If every mistress of a household in this country should demand pure foods," he declared, "there would be little difficulty in the courts, and manufacturers would soon cease making things which the mothers of this country would refuse to buy for use in their families."

He added that there would be a cry against the mixing of certain substances with foods to make them palatable. Dr. Wiley called attention to the great importance of purity in such articles as butter, maple syrup, honey, and particularly of all dairy supplies.

"My plea is," he said, "in order to secure pure food in the household that this and similar organizations unite to compel the manufacturers and dealers in food stuffs to stop all adulterations, to stop all misbranding, to stop all coloring, all deception, and furnish the pure, unadulterated, and palatable article."

That is the right kind of doctrine, and bee-keepers will be delighted to support Dr. Wiley in his efforts to have this state of affairs come to pass. When it does come, bee-keeping will be one of the best callings in this country.

W. K. M.

THE NEW POSTAL LAW.

It is just as we thought. Many of our subscribers who were in arrears with their subscription to this journal were so simply by lapse of memory or from inadvertence. Since the Postoffice Department has issued its new ruling many have promptly replied by paying up all past dues, and, besides that, paying for a considerable period ahead. Many have accompanied their remittance with complimentary words for GLEANINGS and its management. These are always acceptable, and the sentiments expressed are

cordially reciprocated by us. We look on our subscribers as our friends—friends in deed as well as in words.

We were a little afraid some of our old friends would take offense at our announcement, but really we have no choice in the matter. The postoffice authorities wish to suppress the never ordered and never stop papers which are only advertising sheets for their publishers. We think most of our readers will perceive the new ruling is really for the benefit of the people as a whole.

A CORRECTION.

MR. C. H. W. WEBER, whose entrance-controller we referred to on page 355 of our March 15th issue, says it is not true that his device is provided with "darkened passageways" as we stated, but air-channels, through which the bees can not go, but through which the air can pass freely. We understood perfectly the construction of the device, but we were unfortunate in the use of the terms.

He says further that it is not intended to have the exitway entirely closed by means of a slide, except only in the very coldest zero weather for a day or two. After this the slide is shoved over to one side, leaving an opening of about one inch wide. This is covered by another wooden slide in such a way as to shut off the light and yet allow a free passage to the bees into the hive. When so used, he explains, there will be no confined bees, and consequently no commotion within the colony as feared by us. Our readers will please note these corrections in connection with page 355.

SAMUEL SIMMINS, OF ENGLAND, A PIONEER IN THE INTRODUCTION OF MANY NEW METHODS AND DEVICES.

In our last issue, page 415, reference is made to the fact that Mr. Samuel Simmins, of Sussex, England, introduced split sections in 1887; but this is only one of some of the numerous devices or methods which have been "discovered" in the last year or so, but which we find were described by Mr. Simmins in his book in 1887, and other writings, twenty or twenty-five years ago.

We will take, for example, plain sections, described and recommended by him; direct introduction of queens; hiving swarms on foundation starters; plural-queen system; thick top-bars to prevent burr-combs; wooden queen-cell cups; perforated cylindrical queen-cell cages (which have recently been patented in this country); division-board feeders; bleaching comb honey; drawn comb in sections; a large space under frames to check swarming; uncapping-machines, etc. While he was not the original discoverer of all these devices or methods, it is apparent that he was an early pioneer in the use of some things, and an originator of others that are now receiving special prominence, and which have been counted as "something new under the sun."

In regard to split sections, Mr. Simmins described minutely in the 1887 and the 1908 editions of his book, "A Modern Bee-farm," the exact, precise method for putting foundation in split sections as described by Mr. J. E. Hand in these columns within the last year.

BE CAREFUL HOW YOU LABEL OR SELL YOUR HONEY; THE NATIONAL LAW ON MISBRANDING.

ONE of the provisions of the national pure-food law is that every article of food bearing a label, or that is sold as a certain product, must not misstate the source whence such food was produced. Applying this to the honey business it simply means that one can not sell heartsease or mountain sage as "white-clover honey" without getting into trouble with Uncle Sam, providing, of course, that such goods were shipped from one State to another.

A case has just arisen between two beekeepers. The buyer has sent us the correspondence, showing that the seller wrote that he had a nice lot of white-clover comb honey to sell. A correspondence sprang up between the two parties. The buyer agreed to take the honey, paying for it cash in advance. When it arrived, instead of being a "nice lot of white-clover honey" it was heartsease and other fall honey, poorly graded and badly packed. The buyer demanded the return of his money, and the amount he paid in freight.

The producer refused to do this, saying he did not guarantee the source of the honey, etc. The buyer, on the other hand, sends us the correspondence to show that the seller was offering a "nice lot of white-clover honey." On the assumption that it was "white clover," and a "nice lot," he consented to send the money in advance. He now has complained to us, suggesting that we "show up" the other fellow through these columns. We are replying by saying that, under the conditions, on an interstate deal (if he represented that the honey was from white clover when it was not), the producer will have to return the money or be liable to a fine of \$500, imprisonment, or both. In this case the party evidently does not know what he is "up against."

We have thought best to mention this incident for the benefit of the few who either do not know or who are willfully regardless of the fact that, when they sell honey to a party outside of their own State, it must be exactly as represented as to the source, otherwise they will be liable to prosecution by a United States officer. It is bad enough to violate a State law, but a good deal worse when a national law is broken.

As we understand it, Uncle Sam does not attempt to adjust differences between producer and buyer if goods are improperly packed, or broken in shipment; neither will he prosecute if the goods are not as represented, except in cases where they are sold as coming from a certain district or from a

certain source when they are not, or otherwise misbranded. No more can Michigan or Ohio cheese be sold for York State cheese. They must be *exactly as represented*.

It is but fair to repeat that only a very few of our readers need to be reminded of this provision of the national pure-food law. The great majority would not knowingly misbrand, law or no law.

GLUCOSE IN AUSTRALIA.

THE *Australasia*, published in Melbourne, Australia, prints the following in its issue of Jan. 4, 1908:

With regard to the company which has been formed to introduce the manufacture of glucose to Australia, a further step forward has been taken. It has been decided to send Mr. W. L. Engelbrecht, Mount Gambier, to America to select the most up-to-date machinery and get all available information as to the best processes for the manufacture of glucose. He will also visit Germany and England, and continue his inquiries there. In America glucose is made most largely from maize, but in Germany from potatoes. The machinery selected will be adapted for both. Mr. Engelbrecht will leave for America per first boat in January. The head works will be in Melbourne; but branches for dealing with potatoes will be established at Mount Gambier and Warrnambool, and in Tasmania.

We are sorry for our Australian friends, more particularly the bee-keepers. What can be the matter with the Australian people that they should desire to eat glucose? Cane syrup is infinitely to be preferred—in fact, glucose can not be eaten until some kind of good syrup is mixed with it. In this country its use has been ruinous to the manufacture of jams and jellies, and certainly it has always been used to lower the intrinsic value of any food in which it is used. In fact, its use is to cheapen or adulterate, *never to improve anything*. It has also created a number of millionaires at the expense of the poorer classes. The Australian bee-keepers will have their markets lessened if this scheme materializes.

W. K. M.

IN TERROR OF PARCELS POST.

THE reporters in Washington are all agreed that parcels post stands a poor chance of being realized at this session of Congress. One reason they assign for this is interesting; namely, that members of Congress are being fairly deluged with letters from country merchants who think that parcels post would be the ruin of their business. As a matter of fact, great sums of money are being spent in creating a public opinion adverse to any movement of the kind. The men who are opposed to this reform are possessed of means, so that there is no trouble in getting funds; but it has been noted they are exactly the same class who resolutely opposed free rural delivery.

On the opposite side, the farmer and his friends are apathetic, and have no paid lawyers or lobbyists to influence the legislators at Washington. It is, unfortunately, true that the average farmer has no inclination to write or time to devote to the question. It is different, however, with the women of the farmer's family. The parcels post appeals to them. By its means they could

send to their home town for all sorts of small orders, such as every housekeeper really needs, without making a journey of so many miles. It is a wonderful convenience, more particularly when any one in the house is sick, or, as is the case with many, nobody is available to go for the goods required.

The only objection made thus far to parcels post is that it favors unduly the mail-order houses. But what are the facts? The mail-order houses do not care for the parcels post, because it is said they have an "understanding" with the express companies. In many instances the express people have greatly helped their business, and it is true they have assisted the mail-order houses in every possible way. In any case, the greater part of all mail-order trade is done by freight, and always will be, so that, after all, the country merchant sides with his old enemy, the express company, against his true friend the farmer, who has always patronized him.

If country storekeepers kept every thing in stock required by the farmer and his family there would be no need of parcels post; but, on the contrary, they keep only the bare necessities of life, and it would be absolutely impossible for them to keep on hand everything the modern housekeeper or farmer requires. The rural dwellers of the United States have little idea of the wonderful convenience of parcels-post service; but they can imagine a good deal. It makes country life far pleasanter for all, more particularly for the women folks, who are almost constantly in need of some small order from "town."

The farmers should consider this matter carefully, and endeavor to influence others so that, the coming fall, every Congressman will be compelled to state whether he prefers the express companies to the farmer and his family. It is either one or the other.

W. K. M.

THE LOGICAL RESULT OF THE GLUCOSE CORN-SYRUP DECISION.

ACCORDING to the newspapers of Chicago, the Corn Products Co. has acquired 1200 feet of dock frontage on the Chicago drainage canal; by leasing the same for 99 years. It has purchased 110 acres of land in immediate proximity, on which will be erected a five-million-dollar plant for the manufacture of glucose on a grand scale. A new town will be built around the factory, to which the name Argo has already been applied.

This shows the tremendous importance of the "corn syrup" decision, for, as already stated, the Royal Baking Powder Co. and the Western Grocery Co. have both acquired immense factories quite recently for the manufacture of glucose. Under the proper name of glucose it was hard to sell, because the general public had learned to dislike it; but under the name of "corn syrup" it has obtained a new lease of life; and the starting-up of three immense factories proves the agitation against it had a solid foundation.

in fact. Had Dr. Wiley's counsels prevailed, it is safe to say these three factories would never have been started. W. K. M.

THE NEW GRADING-RULES FOR WESTERN HONEY: THE PRACTICE OF NOT SEPARATING SECTION SUPERS DISCRIMINATED AGAINST.

THE following letter, received from the Manager of the Colorado Honey-producers' Association, on the subject of grading western honey, will be read, we feel sure, with interest:

Mr. Root:—I am sending you herewith a copy of the new grading-rules adopted by the Colorado State Beekeepers' Association at its last annual meeting.

Experience had shown us that, while our former rules were satisfactory to most of the bee-keepers of Northern Colorado, where the larger part of the crop is always white, there was some dissatisfaction with them in other sections of the State where sometimes a considerable portion of the comb-honey crop is light amber in color and the cappings of the same also off in color. Under the old rules such honey, while it was a nice article of good flavor and appearance, well filled out and capped over, had to be graded as No. 2, although we are told it was very often sold again by jobbers in the East as No. 1 white.

Another matter that received attention in the revision of the rules was the weight of individual sections. We found that the term "all sections well filled" is sometimes misconstrued to mean also a section of honey that is capped over and securely fastened to the wood, but the comb so thin that it could not conscientiously be called a No. 1 section of honey, weighing only 12 to 12½ ounces. Such honey packed with quite heavy sections would bring the weight of the case up to the required standard; and while it might pass through the hands of the jobber all right, it would prove unsatisfactory to the retailer, as the variation in the weight of the sections of honey would be too great to permit their being sold at a uniform price. Not only this, but, according to the views of the committee revising the rules, a standard 4¼ section filled with honey should weigh not less than 13½ ounces in order to be classed No. 1.

As practically all the comb honey produced in the State is full separated, the new rules touch only upon the average net weight of half and non-separated honey without going into details.

The committee has aimed to secure grading-rules which will result in a close grading of the crop according to finish, color, and weight of individual sections, so as to make the handling of our honey entirely satisfactory and profitable to the retailer.

The recommendations cover the most important points to be observed in preparing and handling the crop after it leaves the hive.

Many of your western subscribers would, I believe, appreciate it if these new rules were published in GLEANINGS.

THE COLORADO HONEY-PRODUCERS' ASS'N.
Denver, Col. F. RAUCHFUSS, Mgr.

The grading-rules referred to in the letter above, it will give us pleasure to place at the head of our Honey Column along with the eastern grading-rules.

NEW COMB-HONEY GRADING-RULES, ADOPTED BY THE COLORADO STATE BEE-KEEPERS' ASSOCIATION.

No. 1 WHITE.—Sections to be well filled and evenly capped except the outside row, next to the wood; honey white or slightly amber, comb and cappings white, and not projecting beyond the wood; wood to be well cleaned; cases of separated honey to average 21 pounds net per case of 24 sections, no section in this grade to weigh less than 13-1-2 ounces.

Cases of half-separated honey to average not less than 22 pounds net per case of 24 sections.

Cases of unseparated honey to average not less than 23 pounds net per case of 24 sections.

No. 1 LIGHT AMBER.—Sections to be well filled and evenly capped, except the outside row, next to the wood; honey white or light amber; comb and cappings from white to off color, but not dark; comb not projecting beyond the wood; wood to be well cleaned.

Cases of separated honey to average 21 pounds net per case of 24 sections; no section in this grade to weigh less than 13-1-2 ounces.

Cases of half separated honey to average not less than 22 pounds net per case of 24 sections.

Cases of unseparated honey to average not less than 23 pounds net per case of 24 sections.

No. 2.—This includes all white honey, and amber honey not included in the above grades; sections to be fairly well filled and capped, no more than 25 uncapped cells, exclusive of outside row, permitted in this grade, wood to be well cleaned, no section in this grade to weigh less than 12 ounces.

Cases of separated honey to average not less than 19 lbs. net.

Cases of half-separated honey to average not less than 20 pounds net per case of 24 sections.

Cases of unseparated honey to average not less than 21 pounds net per case of 24 sections.

After receiving these rules we wrote to Mr. Rauchfuss, stating it was our opinion that, had these rules been in effect, some of the complications that arose over that car of misgraded honey, referred to on pages 339 and 358, March 15th issue, might have been avoided. In referring to this particular car he says:

I have no difficulty at all in locating the origin of this car, as it is evident that it was produced in the western part of this State. A good deal of missionary work seems to be necessary yet in that section when it comes to producing and grading comb honey. I was over there last fall and found there is quite a little honey produced yet by people who don't pay any attention to grading-rules, and apparently are not willing to learn, as, so far, they have always been able to dispose of their crop to careless buyers and speculators at somewhat near the figures that careful beekeepers were getting for their crop; and as long as such conditions exist we can not hope for much betterment until the time arrives when such stuff as illustrated on page 358 of GLEANINGS can not be sold at all, as comb honey, and can be sold only for what it really is—that is, cull honey, cut out and sold that way. If you read over the grading-rules adopted by the State association you will find no place mentioned for such honey as illustrated there, and it is not our intention to have such goods as that ever go out of the State. Regarding the use of separators, I want to say that at the present time we have our members (by this I mean the members of the Colorado Honey-producers' Association) in line, so none of them are producing comb honey without separators. Most of them use full separators, and a very few half-separators. During the past season we have had only one small lot of honey which we bought from a farmer in the house, that was non-separated, and it was a poor lot. We therefore graded it over, and sold it in the local market; but to my certain knowledge we have not shipped a single case of unseparated honey this year.

THE COLORADO HONEY-PRODUCERS' ASS'N.
Denver, Col. F. RAUCHFUSS, Mgr.

We may explain that, when we wrote Mr. Rauchfuss, we deplored the fact that some beekeepers in Colorado were still trying to get along without separators, and that we hoped the time would come when all the beekeepers in the Rockies would see the importance of separating their supers. We are glad to see that the practice of leaving them out is becoming obsolete; at all events, the new grading-rules discriminate against such non-separated honey to such an extent now that the producer can not afford not to use them. It was a penny-wise and-pound-foolish policy before; but the conditions of the new ruling will make it even more foolish.

Of course we assumed that the attitude of the Colorado Honey-producers' Association as a whole is plainly against misgrading honey and trying to get along without separators; but it is a pleasure to see that the manager so plainly declares against it. We are glad to say that the great bulk of the Colorado honey on both sides of the Rockies is of the finest quality and up to the grading. It is only occasionally that we run across a bad lot. We find the same to be true of other localities where good honey is produced.

VOLITION OF QUEENS; SHAKING BEES, ETC.

"I should like to have Mr. Doolittle answer the following questions through GLEANINGS, believing that its readers will be interested in the subject.

"1. Does the queen lay more drone eggs as she grows older?

"2. Can the queen lay eggs at will?

"3. What is a worker doing when she shakes her abdomen over the combs with a gyrating movement, doing this on brood-combs over eggs, larvæ, and sealed brood? Some bees following after, seem to be doing something with their heads. I see that a worker that comes from the fields with pollen on her legs does this as well as the other bees, and there must be some reason for it.

"In order to make a thorough investigation of these matters, a one-comb observation hive will be necessary, with squares marked off on the glass, so that certain portions of the comb can be kept track of under all of the development of the brood under or beyond these squares, a memorandum being kept of the whole.

"E. A. NEWELL, Massillon, Ohio."

In answer to the first question I would say that, during the time between the fertilization of the young queen and when the spermatozoa begin to fail, the number of drone eggs she may lay depends almost wholly upon the wants of the bees in the colony of which she is considered "mother." I know that this may be considered as heresy among those who have been telling us, during the past, that a young queen never lays eggs in drone-cells for the rearing of drone brood during her first season of laying; but hundreds of cases, if not thousands, which have come under my observation, prove to me that a queen which has been laying from two weeks to two months will lay just as many drone eggs under the same circumstances as will the queen which is from three to five years old, unless the spermatozoa she has been carrying have partially or wholly failed. With such failure, any queen will lay eggs which will produce only drones, just the same as will the eggs laid before she has mated. I said "under the same circumstances," and by that I mean any circumstances under which the colony wants drones. Such circumstances are generally when a colony is strong enough in bees to begin to think of swarming, with exceptional cases where the bees take it into their heads that they should supersede a queen of the same year's rearing. Where I have had early swarms, or made colonies early by the shaken-swarm plan I have, scores of times, found

all the drone comb in the hive full of drone brood within a month of the time the young queen (which the colony had reared, or which had come from the cell I had given) had begun to lay where the colonies containing them became populous from the amount of brood the combs contained after swarming. I have thought many times of writing this matter up, when I have seen it stated that a queen of the first season rarely if ever lays any eggs for drones that season, but never got around to it.

Twenty to thirty years ago, when I used natural swarming for my increase, I saw many times much drone comb built and filled with drone brood by second swarms; but, as a rule, all after-swarms are not strong enough as to number of bees to wish any drone brood. Then I have many times gotten a young queen at the head of colonies a week or so before the time I expected the honey harvest to commence; and, in order to get a "great big yield" of section honey, I have taken out all the combs not well filled with brood, and those having mostly eggs and larvæ in, filling up the hive with combs from which the brood was just emerging, saying to myself, "Now I have you, for colonies do not swarm with queens which have been laying only a week or so, enough so that they have gotten fully settled down to business," only to have such colonies fill every drone-cell the hive contained with drone brood, and swarm inside of two weeks, just when the honey harvest had nicely begun. From this experience, covering a period of nearly forty years, I am led to say that any and all queens lay drone eggs just in accord with the wants of their colonies, and that the age of the queen has nothing to do with the matter so long as she is capable of laying eggs which will produce worker bees. After she has passed the stage of laying eggs which are fertilized, she becomes what is termed a "drone layer," and can lay no other kind, no matter how much the bees may desire it otherwise.

Regarding the second question, I can see no other answer than yes; as, so far as laying is concerned, the queen is obliged to will to do just as the bees will. In other words, she *wills* just as the colony wills, every time, when it comes to the egg-laying part. She lays only when the bees feed her prepared food in sufficient amount, and, quite often, after the bees have fed her so that she has laid a large number of eggs, if the weather turns bad, they will not allow these eggs to hatch, removing many of those which would hatch at once, and keeping others for an indefinite period, then allowing them to hatch, or destroying them, just as the weather seems to justify. These things have come under my observation quite a few times during May and June in very fickle weather.

But from a portion of our questioner's letter which was not for print I judge that he wishes to ask if the queen can lay either drone or worker eggs at will, as he speaks of the pitch of the cells having much to do with the queen laying eggs in drone comb. Be-

lieving that is what he wishes me to express myself about, I will again answer yes. I have every reason to believe that the queen knows whether she is laying eggs which are to produce drones or those which are to produce workers. Those who read the conversation on drone comb in GLEANINGS for Feb. 1, 1908, will see how I allow in most of my hives drone comb in only one frame, and keep this frame at the side of the hive so that it may be kept unoccupied by drone brood as long as possible. Well, I have often had colonies start brood-rearing in spring on the side of the hive furthest from this comb, and as the season advanced, and the bees desired drones, and before worker brood had come within three combs of this outside comb with drone-cells, the queen would travel clear around those three unoccupied combs and lay in all of the drone-cells, without putting a single egg in any worker-cells all about the margin of this drone comb. Further, in some cases, all along the edges of the drone comb there may be drone and worker cells mixed, when every drone-cell would be picked out and eggs deposited, without a single egg in *even one* worker-cell. As soon as all the drone-cells were occupied with eggs the queen would return to the brood-nest and go to laying worker eggs as she was doing before. I know that there is now and then a case where a queen will deposit eggs in drone comb, a part of which will produce workers, and the other part drones; but in this case I am inclined to the supposition that the "queen wills it," rather than that the size, depth, or pitch of the cell has any thing to do with it. Of one thing I am certain from many observations; and that is, where the bees desire drones *every* cell of this drone comb will contain only drones, no matter whether the cells are a shade smaller, a little deeper or a little shallower, or whether the pitch is different. The only thing which confronts us, then, is, whether there may be times when the bees and queen want worker brood but are prevented because of the size of the cell. To this I should say no, for I have often confined a nucleus, which had a queen just commencing to lay, to cells wholly of the drone size, and had nothing produced from these cells but worker bees. From these observations, I conclude that, where both drone and worker brood are found in drone comb at certain times, the bees and queen are willing to have some drones as well as workers in the hive.

Regarding the third question, I will frankly say that I do not know; nor have I ever found anybody who does. I have asked a great many bee-keepers about this, and the most of them seem willing to acknowledge that they do not know why this shaking process is gone through with by certain bees in certain colonies any more than they know why certain bees from certain colonies will arrange themselves in rows all up and down on the outside of the front of the hive, and stand there and scrape away, up and down, with a swinging motion of the body, for hours and days at a time. Some have claim-

ed that, when this scraping act was begun, the bees intended to swarm soon; but scores of colonies, keeping it up off and on for a month without swarming, have shown the falsity of any such conclusion; and, so far as I know, *all* are alike ignorant as to what the bees are thus exercising for. I have been told many times that this shaking motion of the bees is to loosen the pollen from the pollen-baskets, so that it would slip off easily into the cells when the bee wished to leave the loads; but this will not account for the matter, for, as our questioner tells us, the majority of the bees which go through this gyrating exercise do not have pollen in their pollen-baskets. Then this "gyrating" is confined, as is the scraping, to certain colonies, so that it can not be of universal necessity in the economy of the hive, and for this reason it will be more difficult to come to any direct conclusion in the matter, even if it were possible to do otherwise. I have stood, sat, and lain beside a single-comb observation hive for hours that have lengthened into days and weeks, but I never saw a bee so gyrating in a one-comb observation hive; and until I do find one, the "marked-off squares" will not be needed. Like our questioner, I believe that all are interested in these things, even though it may be of no money value to us, and, like him, I "should like to know what the bees are doing it for," and what the scraping motions are for; but so far I do not know, nor have I found any one able to tell me.

Dr. Miller says, page 7, Jan. 1, that bees when taken from a cellar can be placed without reference to former location. True; and, more, they can be moved at almost any season if a board or other obstruction is placed in front of the hive for a few days.

Page 8 the doctor wonders if there is not a larger proportion of Prohibitionists among bee-keepers than any other class. I believe he is quite right. I remember attending a large convention of bee-keepers some years ago, when it seemed as if nearly all were of this persuasion; and, more, a large number were in favor of a party for carrying their principles into effect.

On page 84 Stenog gives some rules from C. J. H. Gravenhorst, republished in the *Bee-keepers' Review*, as to why some colonies do so much better than others. Now, it seems well to know why it is; but can we not, while aiming at this as an ideal condi-

tion, spend our time more profitably on a few more colonies than in trying to bring all up to this standard?

A. I. Root's advice to rest, page 104, before eating is (to those not very strong) one of the best things between the covers of the Jan. 15th issue of GLEANINGS: and if heeded it is well worth more than one year's subscription. Better by far take the rest before than after, but better after dinner than not at all.

I fear your editorial on page 18, on the "big field for bottling honey," is somewhat overdrawn so far as New England is concerned. Few stores here in this section that can be persuaded to sell bottled honey, but they have an opportunity to do so, and a single firm in a single year has put out as much as 17 carloads of extracted honey.

Mr. Holtermann, in reporting the Michigan convention, page 99, says Mr. Aspinwall advocated continuous passageways between brood-frames and sections, as it gives better ventilation, and the bees can go in a straight line to reach the sections. This is all very beautiful in theory, but I fear not in practice. I believe Mr. A. has great faith in ventilation. All right; but if too free communication is given, bees are more apt to carry up pollen, and the queen to lay eggs in sections, to say nothing of the bits of dark wax or cappings to injure the appearance of the finished section.

Glucose! glucose! glucose! corn syrup! corn syrup! corn syrup! If a man steals a loaf he is a thief. If he robs a bank of \$100,000 he is only a defaulter. If a man mixes 10 lbs. of glucose with 90 lbs. of cane syrup it is adulterated; but if he mixes 90 lbs. of glucose with 10 lbs. of cane syrup it is corn syrup.

Well, defaulters are not so respectable as they used to be; and if the so called corn syrup is as bad as represented, the people will soon find it out, and the reputation of the offspring will be no better than its ancestor, glucose. Let us be patient. Meanwhile let the people know how it is made.

Some very interesting facts and articles have appeared of late in GLEANINGS in regard to feeding bees for winter. J. L. Byer, page 99, prefers to feed syrup made two parts sugar to one of water. This has been my rule for many years. But unless I mix some honey with it there is apt to be some loss by granulation.

Along this same line E. W. Alexander, p. 99, says, "If it requires 20 lbs. of honey to winter a colony, this additional surplus would be worth at wholesale about \$1.50. Now, if in its place we use 14 lbs. of sugar to make 21 lbs. of very thick syrup, costing about 75 cents, or half the amount the honey will bring, there is a saving of over \$400 in an apiary of 600 colonies; besides, the bees are given a much safer and better winter food." I believe no one will dispute the statement that the sugar syrup is a safer food, as a rule, than honey—especially late-gathered

honey. But that 14 lbs. of sugar made into 21 lbs. of syrup, and fed to a colony of bees, is equal to 20 lbs. of sealed honey, there may be, it seems to me, some question.

Dr. E. F. Phillips tells us in "Miscellaneous Papers on Apiculture," pages 7, 8, that the water in thoroughly ripened honey will not exceed 25 per cent, and is generally not more than 20; and some very ripe honeys will have as little as 12 per cent of water, while the thick syrup that Mr. Alexander speaks of, page 29, is 33½ per cent water. It would seem that this extra 13½ per cent of water must be eliminated before we can get a correct comparison of the actual feeding value of the sugar. To this must be added the loss caused by the activity of the bees in storing the sugar syrup, and for wax for capping, so we can not safely figure on more than 18 lbs. of sugar stored that will be of equal value to the honey extracted. It will probably be less. Thus we must reduce the total amount of honey secured from 600 colonies 1200 lbs., which, at his estimate of 7½ cents as its value, would make \$90. To this must be added the cost of the labor of extracting 12,000 lbs. of honey and feeding 12,600 lbs. of syrup, which might be from \$25 to \$50 more.

Now that I have GLEANINGS for Jan. 1 before me I think I must stir up my good friend Doolittle a little. In answering the questions of T. E. Howe, page 23, Mr. Doolittle assumes that basswood always yields honey when it blooms, and always blooms when not killed by frost. This is undoubtedly true at Borodino, for Mr. Doolittle would no more knowingly make a false statement than cut off his right hand; but what is true of Borodino may not be true of some other places. During the past five years I have seen basswood bloom more plentifully than ever before, and yet fail to yield honey appreciably.

There are places where basswood has yielded even better than for Mr. Doolittle or Dr. Gallup. Mr. O. H. Townsend, of Otsego, Mich., told me last August that he once had a colony that gathered over 40 lbs. (I think it was 45 lbs.) for three days in succession, and would have gathered more, but that by 4 o'clock P.M. the hive was so crowded there was no room for storing more. So it seems to me that much depends on location as well as the amount of bloom. Near the bottom of page 23 he says, "The fruit-buds and leaflets to all trees with which I am familiar are formed in June and July of the preceding year, so the results of next season's honey-yield, so far as the buds and flowers are concerned, are already in embryo on the apparently bare and lifeless branches of the basswood-trees, as we behold them these zero days of winter." Now, this statement is quite true of many fruit-bearing trees as the apple, pear, plum, peach, etc.; but when it comes to the basswood, I believe my friend is a little off. If we look carefully we shall find that the blossom-bud of the basswood comes out of the new or present season's growth of wood at the base of the leaf, or where the present season's leaves join the

stem close to the axillary leaf-bud for next year, and does not form till after the present season's leaves appear. The fruit-buds of the grape are somewhat similar, and come along the new growth of wood opposite the leaves. I have sometimes known frost to kill the basswood-buds, but it was very late when the basswood was partly leaved out, and the new blossom-buds formed on the present season's growth of wood.

I AM "OVERSTOCKED" WITH INFORMATION

When I started in the bee business I was puzzled to know just how many "gums" I could keep. I got a couple of hives and then wondered if that was too many, or if I could keep a thousand. I thought I would keep three or four hives; but one day I happened to find out that a neighbor, only two blocks away, had *six* colonies, and my heart sank within me. All my future hopes as a bee-keeper were blasted. His bees outnumbered mine, and, as I thought, would, whenever a flower had any juice in it, beat mine to it. I wondered if he would not get discouraged and quit. I thought I might buy his bees; but he would not sell, so I watched sorrowfully for my poor little darlings to starve. They did not gather any honey, and I was satisfied that my locality was overstocked, as there were eight hives within a radius of — well, they were all the bees I knew of in the county.

I went to a man who knew all about bees, they told me. In fact, he admitted that he did when I accused him. He had reared queens, he had bought queens, he had imported them, he had done every thing with them; and he told me confidentially that I could get enough honey for table use, if I did not make a hog of myself, provided I kept but eight swarms; but as sure as I kept more I not only would get no honey but would have to feed. It was like this: It takes power to propel a bee through the air; there is no such thing as perpetual motion, and in order to generate that power it takes honey, which was to the bee what coal is to the locomotive. Now, after you have more than eight colonies the bees have to go so far to get enough honey to supply power that it is all digested before they get home, and they starve. Then often, in going so far they are never able to find their way back. This, you know, was not idle theory, but scientific facts. But I thought I would keep a number just for the fun of it, even if I did have to feed. The first year I got a little honey. I increased to fifteen, and got less.

Just as he told me. The next year I increased to thirty, and got still less. Just as he told me. The next year I increased up to sixty, got nothing, and had to feed. Just as he told me. The next year they all did better than they ever did when I had only two. Then I began to think that possibly the crop or something else had to do with success or failure besides the number of colonies. I would just read the bee-journals and find out. I read two articles, and that settled it. The first article said that bees gathering nectar was just like dipping water out of the ocean with a pint measure. It did not make a blamed bit of difference how much you dip out, the plants will all be full again before another bee can poke its nose in, and a few thousand colonies more or less is nothing.

The other article substantiated the first as follows: When bees gather nectar it is just like "shuckin' corn." There is just so much nectar; and when the bees go out and shuck it there is "nothin' doin'" till a new crop is grown. You want only just the right number of bees that will gather all the nectar; and if you happen to count your blossoms wrong, and have a dozen or so of bees more than there are blossoms, why, those poor extra little devils will have to starve, and you, you incompetent bee-keeper, their blood be upon your head! It is often amusing to read the arguments on both sides of the overstocking question; and when there is a failure it is customary to lay it to overstocking. I think a good deal of it is imagination, superstition, or something like it. One writer has nearly a thousand colonies in one place, but they all say he has an extra good place — buckwheat as far as you can see, all buckwheat. He frequently gets a surplus from white clover. In this locality buckwheat never does produce any white-clover honey, but still this is not a good locality.

Here is an experiment that I should like to see tried. Necessarily, from the magnitude of the enterprise, it should be undertaken by some gentleman with philanthropic tendencies. The government might try it. I think it would give us some light on the overstocking problem.

Take an average white-clover locality, and take fifty colonies and set them all on a big wagon-scale. Then take five hundred more, put them on trolley cars and run them up beside the fifty. At night weigh the fifty and record the weight. Then during the night run those that are on the cars away for ten miles or so. Then the next night again weigh the fifty and keep a record. Then bring back the five hundred beside the fifty, and at the end of the day weigh again, and so on till the flow is over. Then average up the honey the fifty gathered when alone and when the five hundred were with them, and see what the difference was, if any.

That would be an interesting test, and before it came off all the bee-keepers could have a guessing-contest as to results. I will register my guess now. I am not theorizing nor arguing — just guessing. My guess is there would be two per cent difference.

FANCY COMB HONEY FROM COLONIES CURED OF FOUL BROOD.

How to get Rid of the Disease without Sacrificing the Honey Crop.

BY R. F. HOLTERMANN.

In connection with this article are shown two engravings of the first-prize honey exhibited at the fruit, flower, and honey show at Toronto, and produced by I. A. Thomson, Britannia, Ont. This was also a portion of the honey which was sent by the Ontario Bee-keepers' Association as a Christmas present to His Majesty King Edward.

spector for the district. Mr. Sibbald, after his arrival, went carefully through the apiary, and out of seventy-eight colonies he found eighteen diseased. Mr. Sibbald then told him that, if he liked, he could cure the eighteen, and wait to see whether any disease would develop in the remaining sixty. Or he might treat the entire lot by following a certain plan outlined, and at the same time secure what crop of comb and extracted honey that might be obtained. The plan recommended and carried out was as follows:

The queens in six of the eighteen diseased colonies were caged, and these six were removed to a secluded spot in an orchard. The bees in the remaining twelve were shaken

FIG. 1.—PART OF THE HONEY SENT BY THE ONTARIO BEE-KEEPERS' ASSOCIATION AS A CHRISTMAS PRESENT TO KING EDWARD.

This honey was produced in sections containing full sheets of foundation fastened with melted wax on the sides and top; $\frac{1}{8}$ inch space was left between the foundation and the bottom of the section to prevent buckling.

Incidentally these engravings show that profit may result, even under adverse conditions, and also that a foul-brood inspector may make himself very useful by dropping a few words of advice which may not cost any additional time.

Mr. Thomson, who is a very thorough and intelligent bee-keeper, stated that, on finding foul brood among his bees, he notified the Hon. Nelson Monteith, Minister of Agriculture for Ontario, at Toronto, as the law requires, and he in turn sent Mr. H. G. Sibbald, of Claude, Ont., who is foul-brood in-

upon starters, and the combs of brood and honey were piled two supers deep upon the six hives with caged queens.

In four days the twelve on starters were again shaken upon full sheets of foundation, and when the comb was nearly completed top stories were given containing full sheets of foundation, and the twelve colonies then run for extracted honey.

There was left, then, only the six diseased colonies with their queens caged, and with two supers each, containing the old combs of the other twelve. These were treated in ten

days as follows: The top stories in each with their combs of brood and bees were removed and placed on a new stand. The bees in the next super and those in the brood chamber were shaken into a hive containing starters, and the queen released, and the two shaken hives again piled on top of one of the former top supers removed to the new stand.

In four days the shaken hives were again shaken upon full sheets; the starters as in the first case were taken to the honey house and rendered into wax.

These last six hives treated, being strong in bees, were given section supers containing slatted separators, wide frames, and $4 \times 5 \times 1\frac{1}{2}$ sections filled to within $\frac{1}{2}$ in. of the bottom, with sheets of extra-thin section foundation attached to the section at the top and at the two sides by means of a brush and melted wax.

In four days the old hives remaining were shaken on starters followed by a shaking

foundation and received no second shaking. These were run for comb and extracted honey, the same as were the foul-brood colonies; and although only a medium year in the locality, at the end of the season there were 88 colonies in good condition, 3000 lbs. of extracted honey, 1000 lbs. of comb honey, and 1100 lbs. of beeswax.

The above plan necessitates careful work, and care must be taken not to expose diseased comb or honey to the bees. Mr. Thomson felt sure he had a clean yard when through. Every thing was done when honey was coming in. Every scrap of the old comb was melted into wax, the refuse burned, and a thorough cleaning-up was effected. The plan is well worth giving to beekeepers, particularly as there is so much foul brood in some sections, and as this method not only does not interfere with the honey crop, but leaves the apiary in 99 cases out of 100 in better condition than before.

Biantford, Ont., Can.

TRANSFERRING.

A Beginner's Experience in Cutting Combs from Old Box Hives and Transferring them to Modern Hives.

BY F. DUNDAS TODD.

[Several years ago, after we had made several hundred pictures, some of which appeared in these columns, and having read various books on photography designed for amateurs, we decided to take some journal devoted to the art in order that we might keep abreast with the times. The *Photo-Beacon* was recommended; and having subscribed or it we were delighted with its contents—especially the editorials.

Not long after, a correspondence sprang up between its editor, Mr. F. Dundas Todd, and the editor of this journal. The former was seeking pointers on the subject of bees, and we were equally anxious to gather pointers on the art of making pictures. The result was a pleasant correspondence, during which we "swapped" ideas.

We said we were delighted with the editorial work on the *Photo-Beacon*, and so we were. Mr. Todd the editor, instead of writing along conventional lines, adopted the simplest and purest Anglo-Saxon, using short, crisp, and clean-cut sentences. How easy it was to follow him! We could almost see him in his dark-room showing us *how*.

It finally developed that our friend found it necessary to sever his connection with the *Photo-Beacon*, on account of failing health on the part of a member of his family, and go west. He had already been keeping bees in a small way, going into the study of them with all the ardor and intensity of a professional man. On arriving in his new field he began beekeeping anew in a larger way. And now, to make a long story short, he has submitted to us manuscript detailing the experiences of an amateur bee-keeper. When we say "amateur" we do not mean one who is "amateurish," but one who is expert and who takes up the study just for the love of it. Such an amateur is Mr. Todd. Along with the manuscript came a number of photos which it can be readily imagined, would be first-class from the standpoint of a professional picture-maker.

We take pleasure therefore in submitting the first installment, which, we apprehend, will not only be seasonable but particularly welcome to the amateur and to the beginning class of bee-keepers, of which we have many in our GLEANINGS family. The style is the same simple clean-cut English used in his photographic writing; and as one reads the lines he can scarcely fail to understand and to imbibe some of his enthusiasm.

It is but fair to Mr. Todd to state that we are taking the last of the series and putting it first, because it comes at just the time of the year when most persons,

FIG. 2.—COMB HONEY PRODUCED IN A COLONY JUST CURED OF FOUL BROOD.

upon full sheets as before described, the combs being taken away for rendering. These colonies, also being extra strong, were run for comb honey as outlined above. As soon as the sections were well under way, and when they would be considered by most advanced bee-keepers to be too far under way, the supers were raised up and others put underneath.

Now as to the remaining sixty colonies in the yard, which had no foul brood as far as could be seen. Not caring to run any risk, however, and wishing to make a clean job of the apiary, Mr. Thomson carried out the above plan, with the exception that the bees were in every case shaken upon full sheets of

if they transfer at all by the direct method, can do it to the best advantage.

The other installments will follow in consecutive order and at their conclusion we hope to put them in pamphlet form for the benefit of beginners and amateurs who may not have time to read the more extended works now offered for sale.—ED.]

When I started keeping bees in a modern hive I would have scouted the idea of ever having to wrestle with the problem of transferring; yet I had performed the operation in less than three months. That was to be my first and only venture; but in my second year of bee-keeping I transferred twice, and I suspect I shall probably beat that record in my third season, as I am in a locality where gums are many and hives are few, and I am just starting in afresh.

There are two ways of transferring—the direct and the indirect. The latter is by far the more preferable, I suspect; but I have never practiced it, for the simple reason I have always wanted to transfer when the conditions demanded the direct method. I hope to follow in the future the indirect route, but at the same time I do not look upon the other any more as a serious ordeal.

In the direct method the combs are cut out of their original position and transferred to the frames of a regular hive; in the indirect method the *bees only* are transferred, and that gradually, to their new home. It is the first I am about to describe and illustrate.

My first venture in transferring was easy—merely changing the bees and combs from the regular Hoffman frames to the Danzenbaker. Since the original frame was considerably wider than the Danzenbaker, and as the combs were simply perfect, it was no trick at all to cut from the one, trim to the proper size, and place in position in the smaller frame, where they were held in place by a string of loose fibrous nature that was wound round the frames several times and fastened securely. In a week the hive was opened and the strings cut away as the combs were found firmly fixed in position.

My second venture was for a friend who had fallen heir to a colony housed in a soap-box, and he wished them put in a regular hive. This proved a more difficult proposition, but I carried it through all right; but since I did some things rather awkwardly I prefer to describe my third venture, which was the most difficult of all.

The following tools have been found necessary: Heavy hammer, cold chisel, sharp steel knife (a carver is excellent), a saw

(I always have it handy but have never used it); a large empty tin biscuit-box with a hinged lid to receive scraps of comb which can be made useful afterward; a board a little larger than the frames; a table, preferably covered with oilcloth; an empty box whose opening is, as nearly as possible, the same as that of the lower part of the hive to be operated upon; a couple of moderately heavy sticks for drumming with; a pail of water and a towel; a ball of binding-twine, or for small frames a box of rubber bands, which are much handier, and a bee-brush or a wisp

FIG. 1.—DRUMMING THE BEES UP INTO THE EMPTY BOX.

of grass. Since the new hive must necessarily occupy the place of the old one it is better to do the work a little to one side or at the rear of the latter so as to save time in disposing of each frame as it is prepared.

I prefer a clear sunny day when the thermometer shows at least 65 degrees in the shade, so as to avoid as far as possible any chilling of the brood. Of course, there are certain seasons when the free flow of nectar makes them more favorable; but I would at

such times use the indirect method in preference to the one I am about to describe. I suspected the presence of the beeswax-moth in the end of October, and felt they had to be got rid of as quickly as possible, for if I did not I might not have any hive in the spring. Direct transfer is, I am convinced, one to be used on only urgent occasions, because the comb is usually so uneven that it must be replaced at the earliest opportunity; so one is thus brought right to the level of the indirect method, but with lots of muss and extra labor.

Having all your tools brought together, set your table in the most convenient position and place the tools in the order you expect to use them so that you will waste no time hunting for them.

FIG. 2.—REMOVING ONE OF THE SIDES OF THE BOX HIVES.

Assume your armor of defense—veil, gloves, and do not forget strings around your trousers at the ankles, as myriads of bees will soon be crawling everywhere on the ground.

See that your smoker is in first-class working order, though it is probable you will find little use for it after the start, because the ordeal about to be inflicted on the colony will in all likelihood thoroughly demoralize its members.

Begin by puffing a little smoke into the entrance. Wait a minute; then give them another dose; repeat a little later. Wait two minutes or so, then lift the box hive off its stand and place it on the table upside

down; then place the new hive-body (empty of course) in the place the box hive occupied. It is desirable to get at least one frame of brood and honey into the new hive as quickly as possible, so that the flying bees will find an abiding interest in the new conditions.

Now on top of the box hive place the empty box, upside down, and proceed to drive the bees up into it by vigorously thumping the sides of the box hive with the sticks provided for that purpose—Fig. 1. The more bees you drive up, the better; but at this stage I could never get much over a pint to vacate the combs. However, as the work proceeds they will continue to come to the top, and I generally jar them off into the box each time I cut out a comb.

TRANSFERRING THE COMBS.

The next thing to do is to cut away one side of the box hive, Fig. 2. Still keeping it upside down, place it at some convenient height, and commence operations by driving the cold chisel between two of the boards. With a flimsy box the wood will probably split away; but with heavy lumber you will probably have to cut the nails with a chisel. At any rate I have never found any difficulty in removing one side of the box hive.

The combs will certainly not be in the fine shape and condition in a properly cared-for hive, but they are more apt to be curved and twisted in many directions; besides, if old they will be not only black, but so hard it will seem almost impossible to cut them with a sharp steel knife; in fact, the first temptation is to use a hatchet.

On the table place the board that is slightly larger than the frame. Some recommend a folded newspaper or cloth on top of that so as to protect the brood from injury as far as possible; but it gets so sloppy and inconvenient that I have discarded its use.

With the sharp knife, used as if it were a saw, slice the first comb from the sides of the box, and then cut it away from the top. The comb being free, lift it and clear it of bees by giving it a sudden jerk above the empty box. If it be old and hard it will stand such rough treatment; if new, brush off the bees with a bee-brush or a wisp of grass.

Now place the comb on the board; take the first frame, and adjust it on top of the comb so as to take the best of it. You want to save as much of the honey and brood as you can. If honey is coming in freely you will have less worry about the stores; but if you transfer in the fall or early spring, then save as much of the honey as you can. Therefore adjust the frame to include as much of the upper part of the comb as possible. Since these combs will probably be discarded at the earliest opportunity, one need not be very careful as to the direction in which the cells are turned; but, all the same, as far as you can, let the comb that was at the top of the hive be at top of the brood-frame.

Your frame adjusted, take the carving-knife and mark out on the comb the inside

FIG. 3.—OUTSIDE OF THE BOX HIVE REMOVED, SHOWING THE APPEARANCE OF THE INTERIOR.

dimensions of the frame. Then remove the frame and cut right through, but preferably keeping to the outside of the bounding lines so that, when you replace the frame, the comb will have to be squeezed into place. If the original comb was both longer and wider than the frame your task will be easy; but this rarely happens, even when transferring to small frames, and so you will have gaps at the corners and ends. The remedy is easy: Put a piece of comb larger than the gap on top of it, never minding how the new piece is turned; then cut through both combs; remove the trimmings, and force the new piece into the hole, where, of course, it will fit perfectly. All this is a long story, but in practice I find it takes 45 minutes from the first puff of smoke to the moment the cover goes on the new hive, so about three minutes is time enough to spend on each frame.

You were advised to place the comb on top of a board. You will see why. The frame has to be brought to the perpendicular; and if you try to lift it bodily the pieces of comb will simply fall out; but by

means of the board both frame and comb are tilted safely to the proper angle. To secure the combs in position I find rubber bands more convenient than strings. The size depends upon the frame, of course; but, roughly speaking, they ought to be, when unstretched, about one-third the width of the frame. An assistant can slip these on in a few seconds, the frame being projected over the end of the table for the purpose. Four is an average number for a frame. If rubber bands are not handy, then a soft string, such as binder-twine, is good. Make two turns at one end of the frame so as to catch one end of the string; then wind to the other end of the frame; cast a loop, or make any kind of a knot, and the job is done. Get the frame into the hive as quickly as possible, so that

FIG. 4.—BOX OF BEES PLACED IN FRONT OF THE ENTRANCE OF THE HIVE.

the bees will have something to care for. Never mind the slop on the frame; the bees will take care of that right away, and probably get more assistance than either you or they care for.

Before starting the next frame, clear the table of the trimmings by dropping them into the tin box, and closing the lid. Before your job is finished you will probably draw from this store; but in the mean time you want the fragments under cover, to be free from the annoyance of thousands of bees that are naturally attracted by the smell of honey. Turning to the box hive you will find a host of bees on top of the combs. Jar them off into the empty box, and proceed with the second comb and the second frame. If you find brood here, be as gentle as you can. Do not kill any life wantonly or even carelessly. I know it is impossible to make omelettes without smashing eggs; but one need not smash eggs when omelettes are not being made. Besides, bees cost money. Bees and honey are convertible terms. Bees make honey, but honey is made into bees. Therefore both humanity and business protest against the careless destruction of life.

If the weather be at all cool, one can not proceed too quickly with the brood-combs to get them into the care of the bees as speedily as possible.

The instructions for filling one frame apply equally to all others; but this may be added: Get the combs as even as possible, and never hesitate to cut out a piece that is too thick, as it will interfere with the future handling of the frames. Again, in piecing out, try as far as possible to cut pieces that will reach from top to bottom of the frame, as the wedging-in gives more certainty of the comb staying in place. And do not forget the reserve stock in the tin box.

Once the frames are all in place and the cover on the hive, place a board running to the entrance and set the box with the bees on it (open end, of course) toward the entrance, and the procession will soon start homeward, Fig. 4.

PREVENTING ROBBERS.

Last of all, remove the honey mess as quickly as possible, so that you will not encourage robbing. Even with only one hive in the yard, and the nearest apiary quite a distance away, it is simply amazing how speedily a well-defined line of travel one can see in the air. So at once carry the old box hive at least one hundred feet from the scene of operations; pick up all loose fragments of comb, and dispose of them in the covered tin box; then wash the tools and table as speedily as possible. A few minutes' playing with the hose-pipe is very effective.

The last time I transferred was toward the middle of November. The day was warm, with no wind. I worked on the south side of a thick hedge so that the conditions for comfort were ideal. The task was finished by two o'clock; but before the bees were all in the hive a perfect cloud of robbers had gathered from far and near. To protect the hive I flung a liberal supply of damp grass

on the entrance-board, leaving it there until four o'clock, when the chilly air drove the visitors away. The grass was removed, so that those which rightfully belonged there could find admission.

The robbers returned for at least two days; but I was on the alert, and at the first hint of their presence I applied the wet grass. The unwelcome visitors held the outside of the hive for the best part of these two days, but after that a very contracted entrance seemed sufficient.

The scrap comb was strained of its honey over the stove, then diluted and fed back to the bees in an Alexander feeder, giving about a pint each day. At the end of a week I opened the hive, examined only one comb, but found it in fine condition; so with a sharp knife I cut the rubber bands, which snapped back to the bottom of the hive. The bees are now carrying them out at their leisure. On the same day I cleaned the bottom-board. The hive was exceedingly strong in bees, but I found hundreds dead on the bottom. I think the chilly night had killed off those that failed to get into the combs, as in my present locality the thermometer touches 32 degrees every night during the winter months.

A few moth larvæ were found, but not enough, I think, to have hurt much; and since the transfer a couple have been found outside the entrance.

December 9, a month later, young bees were sporting in goodly numbers, so that, apparently, all is well. A few bees were carrying in pollen of a light yellow color. The source of this is unknown to me. The only bee-plant I knew to be in bloom was alfalarela; but the blossoms were few, as its season is not due until February, so far as I can learn. There also lingered on the stage a small quantity of second-growth sweet clover.

Medford, Oregon.

MOVING BEES IN CAR LOTS.

Some Timely Suggestions from One who has Learned by Extensive Experience.

BY E. D. TOWNSEND.

There is but one good time to move bees, and that is at the period in spring when the hives are the lightest in bees and honey. In this location this is about the middle of May. Our plan is to watch the progress of the season to see whether it is late or early, and occasionally to look through the swarms in order to keep posted on the time when the colony is weakest in bees and in stores. This will be when the last of the old bees have died, and when their places are filled by young bees just reared, which are not, as yet, very numerous.

PREPARING COLONIES FOR MOVING.

If the bottom-board has a deep side, place this side up, and fasten with four box-staples, which should be put on the sides of the hive,

as it is not satisfactory to put staples on the back end for moving on a car. When both sides of the bottoms are stapled, two staples to a side, as shown in Fig. 1, there will be no danger of their being bumped off in transit.

FIG. 1.

As many wire-cloth frames will be needed as there are colonies to move. These are to be nailed on the top of the hive, after removing the cover, and are for ventilation. Ask the hardware man for black window screen (other colors may do just as well, but I prefer the black); and if the right width is purchased it will cut to good advantage.

The wire cloth should be the size of the top of the hive, outside measure. As the lath are $1\frac{1}{2}$ inches wide, cut four pieces $1\frac{1}{2}$ inches shorter than the length of the hive, and four $1\frac{1}{2}$ inches short of the width, and make the frame as shown in Fig. 2, in such a way as to mismatch the pieces at the corners, which will be double thickness. With the inch nails that are sold for bee-keepers' work nail through both sets of lath and the wire screen, especially at the corners. If bass-wood lath is used and the nails clinched, the

FIG. 2.

screen ordinarily ought to last a lifetime, and it will be much more handy than simply a piece of wire cloth fastened with loose lath or strips that are always being lost. The screen is to be fastened on the top of the hive with four 5-penny box nails, one at each corner, driven into the side board of the

hive. As this screen affords ample ventilation for May moving, a lath is nailed over the entrance to shut the bees in. It is very harmful to keep bees shut in their hives, and we aim to plan so that all of the entrances are left open until the morning the car is to be loaded. If the colonies to be moved are far from the depot they are moved in by wagon, unloaded in some convenient place, the entrance-blocks removed, and the bees allowed to fly until the morning they are to be put in the car. It is very important to have every thing handy, for the work should all be done in one day, and the bees started toward their destination at the earliest moment.

HOW TO MOVE BEES ON A WAGON.

Some may want to know how we move bees from an outyard to the car. This is done on a common low-wheeled farm-wagon. We put on a set of bolster-springs and then a flat hay-rack. If there is no front rail or dash, a narrow board is nailed across the front edge of the rack to keep the first row of screened hives from being jostled out of position.

The hives are loaded so that the frames are crosswise of the rack; and if they are of the Langstroth pattern, ten or twelve rows of four hives each can be put on crosswise. One tier high will make an ordinary load. When all are on, a narrow strip of board is also nailed along both sides and the back to keep the hives from sliding off.

THE KIND OF CAR TO SHIP IN.

The agent of the railroad company should order a single-deck stock or cattle car for the day the hives are to be loaded. A non-ventilated box car should not be used, for hot weather may come before the bees get to the journey's end, and there would then be trouble in ventilating. As an illustration of the importance of making use of a ventilated car I will cite an instance that happened here in Michigan a year ago. A party moved a car of bees in a regular box car, and provided no screens for the tops of the hives. The combs in seventeen of the best colonies melted down, and other colonies were so reduced in strength that they were of but little use that season; in fact, there would not have been a single colony to go through without smothering had it not been that the trip took but two days, and these two days were during some of the coldest weather in the spring. I believe, then, that it is best to have in all cases a well-ventilated stock-car, and to provide screens for the top of each hive.

LOADING THE CAR.

The car should be placed, as nearly as possible, to the colonies so that they can be conveniently loaded. In placing the hives in the car every thing must be braced rigidly to prevent shaking and jarring any more than is necessary. It is important to remember that there is no side shaking to speak of, so all of the bracing should be done with the intent of preventing the lengthwise shaking. A few hundred feet of 2×4 scantling will be needed, and also a few 16-ft. pieces of 2×6

timber. The 2×4 's will need to be 16 ft. long for a 36-ft. car and 14 ft. long for a 33-ft. car, for they must be long enough to reach from one end of the car up to the doorway. These 2×4 's are to be placed lengthwise of the car

FIG. 3.

over the first tier of hives, to act as a support for the second tier. The 2×6 pieces are to go across the car between the last row of hives and the doorway. In this way each tier of hives can be keyed up tight with covers, etc., so that there will be no unnecessary jostling.

After sweeping out the car, fill one end nearly to the door with one tier of hives placed directly on the floor. Before reaching the doorway with the last row of hives, cut one of the 16-ft. 2×6 pieces in two in the middle, which will make two pieces 8 ft. long. One of these will be just the right length to reach across the car, and it should be placed flat on the floor against the car-door-post and on the side of the post toward the bees. There will probably be a space between the edge of this two-inch piece and the last row of hives put in, and this space should be filled in with covers or bottoms or some other material, for it is very important to have the hives placed and held so close together that there can be no movement endwise of the car. Six ten-frame hives, if there are no projections on the sides, can be placed in each crosswise row, for, of course, the hives should be loaded with the frames parallel with the rails. If eight-frame hives were used, possibly seven could be put into each crosswise row.

After the first tier of hives is loaded so that the floor is covered on one end of the car up to the doorway, and keyed up firmly, as before explained, seven of the 2×4 scantlings are to be placed parallel with the car on top of this first tier. One of these is put at each

side of the car, and the other five spaced equally between them, so that the next tier of hives may rest on them. (If these 2×4 's were placed crosswise, the hives would be more likely to get shaken off.) In order to give a larger surface for the rows of hives to rest on, the 2×4 's should, of course, be laid flat. This will allow a two-inch space between the first two tiers of hives, which is ample to give good circulation. The subsequent tiers are loaded in the same way.

By this plan we have moved three cars of bees from Remus to the northern part of the State during the month of May. However, when we do any further moving we propose putting 2×4 's crosswise of the car also, between each tier, so that there will be 4 inches of space instead of only two. In this way there will be openings at the sides as well as at the ends of the car, and we are sure it will be sufficient, since there would be circulation from all four sides and also up and down at the ends of the hives where the hand-hole cleats hold them apart $1\frac{1}{2}$ inches.

If bees only were to be moved, probably four hundred colonies could be put in, using both ends of the car. However, we once moved nearly two hundred colonies of bees in one end, while about one-half of the necessary fixtures belonging to them were placed in the other end. The rest of the fixtures were put into a regular box car without any crating. The goods in this second car were billed at 600 pieces weighing 4000 pounds. We paid by the hundred-weight and not for

O. H. TOWNSEND'S PLAN FOR LOADING THE HIVES IN THE CAR.

It will be noted that the two tiers of hives are separate, and that access can therefore be had to any hive in the car.

a full car. Since I did not wish the car of bees to arrive before the other car did, I asked the agent to blanket the shipping-bills; but he said he knew no way of doing this. However, I asked him to pin the two bills together, which I believe he did finally. As

there was a car shortage at that time I knew it would be quite difficult to hold this one car that contained only 4000 pounds. I had found that the agent could not bill both cars together, so I counted up all the pieces I could find in the supply-car, and found there were something like 600, as before mentioned. As good luck would have it, the two cars started out hitched together. We went over four different divisions of railroad; and at each division, armed with a shipping-receipt calling for 600 pieces, I went to the agent and asked him to let this car of supplies go through with the bees. If he did not seem to be inclined to grant the request I would mention the fact that there were 600 pieces in the car to transfer, many of them in poor shape to handle. The consequence was I had my way at each point, and both cars were sidetracked together at the destination.

If not too many colonies are to be moved, the hives might be tiered up along each side of the car, leaving an alley in the center between, so that one could walk the whole length of the car. Better ventilation could be afforded by this plan.

In moving bees in hot weather, when the colonies are more populous and the weather such that it is necessary to have more ventilation, an empty story might be placed over each hive with the screen on top, thus giving a large clustering-space for the bees. While I have had no experience in moving bees by railroad in hot weather, my experience in moving by wagon would convince me of the necessity of this additional clustering room at all times when the weather is hot.

Mr. O. H. Townsend has had considerable experience in shipping bees; and concerning this part of the subject he writes as follows:

My experience in shipping bees has taught me that it is best to load them so that it will be possible to have access to any hive in the car if necessary. In order to accomplish this the upper tier of hives must be placed some distance above the lower tier instead of resting upon it. This leaves every hive in the car so that it can be moved independently of any of the others. The engraving on the preceding page gives an idea how this is done.

In order to save all brood it is best to feed *en route* with thin sugar syrup. The barrel indistinctly shown in the engraving is for the purpose of holding the sugar. Last spring I shipped the colonies late, and so had a shallow Heddon case on each hive with the screen on top of this. An Alexander feeder made just right for fitting lengthwise in each hive, and resting on the tin rabbets, was filled and placed in each hive the day before the colonies were taken away. These were also filled again as the bees were loaded into the car. The feed was poured from a common garden-sprinkler with the perforated end removed.

Even in hot weather it would be better if one could get the air to the bees without the light shining in, for this light keeps the bees trying to get out.

One who has never moved bees in car lots by freight has no idea how much the cars are bumped together in switching. Anybody in the car will be almost knocked from his feet, and the first thought is that every comb in the hive will be broken down; but if the combs are a few years old there will be no breakage. It is not necessary that the combs

be wired to stand moving, but they should be two or three years old so that they will be well fastened to the frame on the ends as well as the top. Combs used for brood-rearing are also tougher and less easily broken than those that have not contained brood.

Bees in car lots go by freight at a second-class rate on 12,000 pounds. If the car goes to a station where there is no agent, as will be the case many times in shipping to a new location, the freight will have to be prepaid, and there will be no siding privileges included in this. In other words, in shipping to a prepaid station or over a different road, the car can not be sidetracked at different points for the purpose of taking on more bees along the line. In shipping from Remus over the Pere Marquette Railroad we can get the car sidetracked at any point along the line by paying \$3.00 as a minimum charge. If it is necessary to sidetrack on some different road the matter must be taken up, of course, with the officials of that road.

In order to make the best headway with the car, find out from the agent the time when the car will be transferred to the next division of the line or to the next line, for it sometimes happens that the car would have to wait for several hours before being transferred. In such cases always have the agent ask the division superintendent for permission to have the car transferred immediately after arriving at the point of transferring. In asking for this privilege, always present the argument of *very perishable goods*. It is then necessary to see the agent of the next division, or road, as the case may be, and tell him that there is a car of very perishable goods on the transfer siding, and ask him to get it off on the very first freight. I always ask if there is any through freight that might get the car to destination first, for it is always best to wait a little longer if a through freight can be made use of that will save a little time in the end. There is also less jarring because of the shorter number of stops, etc.

On arrival at the destination the hives should be unloaded, placed on the permanent stands, and the entrance-blocks removed as soon as possible, for the bees seem to suffer most when confined if the hives are not being jarred. A neighbor once moved two wagonloads of bees in very hot weather. The hives were placed on the new stands about noon, and part of the bees were not allowed to fly until the next morning. The result was that these colonies that were confined were suffocated, for the combs were melted down. When there is danger of suffocation on the car, water should be sprinkled on the bees frequently with a sprinkler in order to keep the temperature down. For this purpose a couple of five-gallon cans should be kept filled with water, to be used in case of an emergency. A lantern will be found necessary also. If the destination is reached during the night the colonies may be unloaded early in the morning, as the bees will keep quiet during the night.

Remus, Mich.

FALL AND SPRING FEEDING.

When to Feed Thick and when to Feed Thin Syrup; Syrup vs. Honey as a Winter Food.

BY E. W. ALEXANDER.

Feeding is becoming a very important part of our business, and from the many letters of inquiry I am receiving from parties in many places I find some bee-keepers have rather erroneous ideas of the proper way to do this work in order to secure the best results, and at the same time avoid all danger of the feed entering the supers. There is no question but that we can secure very beneficial results by judicious feeding in early spring as well as late in the fall; but we must be careful to do it so no possible harm can come from the practice. I would advise having every thing as handy as possible before commencing this line of work; for after it is commenced there should be no stop until the weather becomes warm and settled, except on fair days, when the bees can gather nectar from the flowers.

Before taking our bees from the cellar we have our feeders all ready, and the necessary barrels of sugar for spring use in our bee-house; then with an agricultural boiler which holds 45 gallons two men can make the necessary syrup and feed six or seven hundred colonies in less time than we could formerly feed fifty. It is the advantage secured from taking these short cuts on both time and expense that I have called your attention to so often.

There are only a few conditions a colony is likely to be in when it is necessary to resort to feeding. First, in the spring, if the bees have little or no honey they should be fed at once five or six barrels to prevent starving. This syrup should be about the consistency of good honey; then to stimulate brood-rearing it is far better to feed a much thinner syrup. I find that, if made of 1 lb. of sugar to 3 lbs. of water, it will give the best results. This furnishes both food and water mixed together, which is very necessary to encourage early breeding.

Then before the close of the season, if there are some colonies rather weak in bees, also light in honey, they should be fed daily two or three pounds of either extracted honey or sugar syrup. This should be one-half sugar to one-half water, which will encourage fall breeding and also add somewhat to their winter stores.

For the principal winter food the colonies should have a syrup made of the best granulated sugar, one pound of water and two of sugar. This should be boiled well until the sugar is thoroughly dissolved. Some think it necessary to add a little extracted honey or tartaric acid to prevent the syrup from crystallizing. We rather prefer this addition, but have had good results without it.

Feeding for winter stores should be done late in the fall, about two weeks before putting the bees in their winter quarters; and whatever amount they require should be given them at one time.

When feeding at any time or for any purpose we must use good judgment; otherwise we may thwart the very object we wish to achieve. First we must be very careful to feed just enough, and no more than the necessary amount to secure the desired object. When feeding in the spring, give only enough for daily use of the thin syrup; and if there is a spell of a day or two that is fair, and the bees are getting some nectar from the flowers, then stop feeding until the weather becomes unfavorable for them to work, but don't stop unless you are sure that the flowers are yielding nectar. If you watch your bees and the weather closely you can stop feeding as it becomes more pleasant, so there will not be any syrup left in their combs.

When feeding in the fall for winter stores, we must be careful to feed only enough to furnish them with the necessary amount to last during their long confinement. I think it best to feed all colonies 15 or 20 lbs. of *thick* sugar syrup late in the fall; where a colony has as much honey as it requires for winter use, or more, I would remove two combs of their honey from each side of their hive early in the fall. Extract these four combs and return them near to the center of the hive; then when giving them their winter food they will store it in these center combs, and cluster on them during the winter. In this way they will use up all the syrup you have given them, and there will be no danger of any being left to enter the supers.

We must be careful how we feed, to avoid all harm, and at the same time secure those good results from feeding.

If we gave our bees a lot of thick syrup in the spring it would be of but little use to stimulate breeding, as they require water at that season as much as they do honey. Then if we gave them the thin syrup in the fall, such as they require in the spring, it would be one of the worst things we could do, as it would cause almost every colony to have the dysentery before mid-winter.

You may think that, if a colony requires feeding, it is of but little consequence when, how, or what it is fed; but there is a right and a wrong way to do all things, and our bees are certainly very exacting in their requirements. There is a great deal to be gained in turning sugar syrup into bees in early spring, and by it saving their lives during the winter; but remember, even if the law would allow us to do it there is not a particle of profit in feeding sugar syrup to bees to get them to turn it into either comb or extracted honey.

In one of my articles last fall I spoke of our feeding 200 colonies sugar syrup as a substitute for honey during the winter. Before feeding we removed nearly all the honey from these colonies, and now after five months of confinement they are in perfect health, and, without a single exception, have wintered well. They are as bright and lively as we could expect to see them in June. We are so well pleased with this experi-

ment on a large number of colonies that it is rather doubtful if we ever again depend on honey as a winter food.

I think Prof. A. J. Cook, nearly forty years ago, was the first man who called our attention to this very important subject. It was at a bee-keepers' convention in Utica, N. Y., and I can never forget how anxious father Quinby and Capt. J. E. Hetherington were to inquire all about this substitute for honey as a winter food, which at that time was a new discovery. If his advice had been taken then it would have saved the lives of far more colonies of bees than there are to-day in the United States.

Delanson, N. Y.

[When this article was written Mr. Alexander had not seen the special series of articles on spring management that appeared in our two March issues, wherein *spring* feeding, except to prevent starvation, was considered ill-advised. Even if he had seen them, it is presumed that his advice would have been just the same, except that he probably would have presented some arguments in defense of the practice for his locality.

As we have before pointed out, our correspondent has a late honey-flow, mainly from buckwheat, and therefore this must be taken into consideration.—ED.]

THE PLURAL-QUEEN SYSTEM.

A Review of the English and American Systems; Their Advantages and Disadvantages as Viewed from the Standpoint of a Traveling Bee Expert in England.

BY J. GRAY.

In this article I propose to review briefly the various conditions under which two laying queens will live in peace in one colony.

PLURAL QUEENS UNDER NATURAL CONDITIONS.

When supersedure takes place in a colony of kindly disposition the old queen is allowed to continue while the young one takes up the duties of motherhood. The forces that go to make up this variation from the normal conditions of a colony are twofold—disposition and plenty. The bees of a colony of kindly disposition will extend their kindness to the old queen, neither workers nor young queen showing fight; and while stores are pouring into the hive the old queen still finds some workers to feed and care for her. Here, then, is one of the vital points: Under what conditions can I get a colony to feed two queens, without which all our efforts will fail? Note how easily the hundreds of drones are disposed of, all for want of food. It is not a question of drone fighting drone, but it is a question of starvation. When those conditions arrive that a queen begins to restrict her laying because she is not fed so lavishly, then comes the time that one queen is neglected and starved. It is here that Alexander is beaten by the bee.

THE ENGLISH SYSTEM.

Our Wells hive provides for the two colonies becoming one in scent and heat, only until harvest time, when the two forces are worked together in one common super. I pointed out in my last the greatest fault of the system; *i. e.*, the big unwieldy hive. There is also another fault that comes through the two colonies carrying the same scent.

Dr. Miller has called attention to the fact that a colony will use one side of the hive more than the other. It is just this that causes trouble with the Wells—both colonies carry the same scent, with the result that, in the early flights, one side increases to the depleting of the other until at last the queen is missing from the weakened side. I have had the same experience when trying to winter tiered-up instead of side-by-side scent, and heat allowed only between the two.

THE ADVANTAGES OF THE WELLS SYSTEM.

The advantages are a big yield of honey and less swarming. The lesson it teaches is that it takes about four days for two colonies to acquire the same scent.

THE HAND SYSTEM.

This has some very good points. The shallow frames make a crowded condition of brood-nest which would tend to favor two queens from the workers' point of view. The queens being kept apart by the excluder, their time is not wasted by useless fighting, even though their stings were cut off, and the frames are shallow enough for two sets to form one chamber with a queen in each set.

Doolittle has pointed out how bees contract with cold, and occupy only half the space. When this contraction occurs there would be the fault of starving one queen, as in the Wells system. Is it possible to modify the Hand system and use a queen-excluder in summer and wire cloth in winter, with an upper and lower entrance? Even then the risk would still remain that the lower entrance might be used the more.

THE ALEXANDER SYSTEM.

This would have been excellent if possible to carry out; but it fails at the most critical time. We want a system that will carry us through the winter. It would be hard on the stock to sacrifice every other queen, and, when the spring comes, raise an equal number to fill up again.

Modern apiculture has guided the bees to perform some wonderful work, yet this problem presents a big difficulty in that we are against the natural instinct of the bees.

Long Eaton, England.

[Mr. Gray suggests the use of wire cloth after the honey-flow, or during winter, instead of perforated zinc; for when a flush of good times for the colony has passed, one of the queens will be missing because the bees favor one more than the other. It is possible, if the cluster were divided by wire cloth, the two queens could be maintained over winter.—ED.]

PLURALITY OF QUEENS.

Points in the Wells System Explained.

BY SAMUEL SIMMINS.

In my 1893 edition of "A Modern Bee Farm" I gave a chapter upon this subject; but in preparing my 1904 issue, the question appearing to have ceased to create any further interest, I gave but a passing notice to the plural-queen methods.

It may interest your readers to know that, some twenty years ago, Dr. Stroud, of Port Elizabeth, South Africa, claimed to be able to work a number of queens in one colony without their killing each other or being disturbed by the workers; but he gave no particulars that would have explained his plan of management.

More recently Mr. Heddon stated that he could run more than one queen in the same hive; but it was reserved for Mr. Wells, of Aylesford, Maidstone, England, to be acknowledged as the first to reduce the matter to practical working as a system in honey production.

The correspondence relating to the matter is to be found in the *British Bee Journal* for 1892, and in the issue for November 10, of that year, after stating he had at first made up his mind to work none but "two-queen" colonies in future. Upon further consideration, and in deference to other expressed opinions, he said: "In order to compare results, and to make the matter as plain as possible, I decided to change my plans and work five single-queened stocks through the season, and very carefully note results.

"It will, perhaps, not be out of place just to say once more that the double stocks have two queens in each, divided in the center of the hive with the thin wood perforated dummy, so that neither queen nor bees can pass beyond their own part of the stock hive; but at supering time a sheet of queen-excluder zinc is placed on top of the frames, and on this the super into which both lots of bees are allowed to run and mix together as they please."

Now, this is just the point which the editor of GLEANINGS has somehow overlooked, for the bees not only mix in the supers, but of course can also, through that medium, mix up into either side occupied by the separated queens. Without doubt any other projected plan of working more than one queen in a hive will come to grief where a similar neutral medium (as to queens) is not allowed. By Mr. Wells' plan there was no uncertainty as to the fate of either queen; as, when the supers were removed, each queen was left where she started. The five double-queen hives gave him 789 lbs. of honey, mostly extracted, while the five single-queen hives yielded 205 lbs.

Mr. Wells used 14 frames in the brood-chamber, each $14 \times 8\frac{1}{2}$, so that, with two queens, he would not have more than six of such frames to each queen, while the single queens had most of the 14 frames. His hives

did not appear to be large enough for the dual-queen plan, as he was troubled with much swarming.

In my 1893 edition I illustrated a larger hive for the purpose than is used by Mr. Wells, with two chambers for each queen, with his perforated divider at the center, and a full-length super, though a sectional super in three divisions would appear to be better for either comb or extracted honey.

At the same time I also gave a sketch of my tiering hive of ten frames, with excluder zinc between each, as another method of working two or more queens in the same colony. I was careful, however, to advise my readers that when

UNITING TWO OR MORE STOCKS

by this plan a small-hole perforated divider was to be placed as a safeguard between each brood-chamber, until the bees were considered mutually good-tempered. These boards were then to be replaced by zinc queen-excluders. A colony of two chambers in this style, if divided in the center of each by a Wells dummy, will accommodate four queens, either with entrances each way, or only one below. Furthermore, with no entrance cut in the rim of the hive, a further zinc-excluder frame may be at the base, with a hollow floor under, thus preventing any loss of queens by swarming. But just here is a question as to disposing of the drones, even if so much zinc is advisable.

It was in the year 1889 that my own experiments were made in holding more than one queen in the same chamber; but at the time I failed to find any advantage in the plan. The queens and combs being divided by excluder zinc, I was troubled by the loss of valuable queens as soon as bad weather occurred, and the brood-nest was restricted; hence there was little encouragement so far as my experience had gone.

COMPARATIVE RESULTS.

That the plural-queen plan can not always be relied upon to give the best results may be gleaned from the following experience with various hives. These bees were on British standard frames, $14 \times 8\frac{1}{2}$, and were worked for comb honey. The results secured by this bee-keeper do not show any advantage for the plural-queen plan, but certainly the reverse, as at the most the double-queen lots show only 40 lbs. to each queen, whereas several single-queen hives gave 80 lbs., and in one case as much as 120 lbs.

No. 1, single-queen, 80 lbs.	No. 6, double-queen, 50 lbs.
" 2, " " 80 "	" 7, " " 60 "
" 3, " " 120 "	" 8, single-queen, 80 "
" 4, " " 70 "	" 9, double-queen, 70 "
" 5, " " 21 "	" 10, " " 80 "

No. 11, single-queen, 78 lbs.

No. 3 appeared to make a big jump in comparison with the rest, and it may be interesting to note this was Simmins' "hanging-chamber" hive. In this hive a super with full sheets of foundation is started beneath the stock; and as soon as the bees cluster upon the foundation the case of sections is placed above the stock, with the bees just as they are, already drawing out the cells.

This appears to me to be the most expeditious way of providing drawn combs in sections, and the above result fully justifies my contention. More detailed arrangement is to be found in "A Modern Bee Farm."

It will have been seen that, in working for extracted honey, Mr. Wells secured higher results with his double-queen hives than with single queens, there being an average of 156 lbs., for his five lots, or 78 lbs. for each. Will there be any advantage in the plural-queen plan? I see none.

Note.—The first intimation of my method of selection by breeding *solely from one queen for one season* was outlined in the *American Bee Journal* for March, 1906, also showing how each selected queen-mother was afterward passed on as the parent or grandparent of the only drones used in the following season, thus always mating back to the progeny of the next selected queen brought into the strain.

Heathfield, Sussex, Eng.

[In looking up the Wells system originally, we did not run across any articles where Mr. Wells mentioned the use of perforated zinc. In the reference above given, he clearly states its use and we accept the correction.—ED.]

THE DUAL AND PLURAL QUEEN SYSTEMS.

Conditions Under which They may be Used; a Review of the Whole Question.

BY J. E. HAND.

Judging from the nature of the argument that has been advanced in opposition to the plural-queen system it would seem that this system is not well understood, even by those who consider themselves sufficiently qualified to criticise it. Therefore the object of this article is to show that the plural-queen system is not only possible but profitable, as well as highly desirable under certain conditions.

It is claimed that the conditions under which two queens are allowed to remain in the same hive are in cases of supersedure, when, after rearing a young queen, the old one is allowed to remain in the hive as long as she lives. Granted that this is true of bees when guided by the hand of nature. It is equally true, however, that, when guided by man's reason and ingenuity, two or more queens may be kept in the same hive with impunity.

It has been found that, while a vigorous queen will not tolerate a rival queen, the bees themselves will tolerate a plurality of queens or any number of queen-cells; therefore all that is necessary in order to keep two queens in one hive is to keep them from getting together. This is done by means of perforated metal, which keeps the queens apart, but allows the bees free access to both queens. Thus we have one large hive with two queens, each queen being sole mistress of her own brood-apartment.

It is hardly necessary to add that these are the only conditions under which two queens may be kept successfully in the same hive. It will be seen that the two-queen system, instead of being an open violation of nature's laws, is the result of a correct knowledge of the habits and instincts of bees.

In discussing matters pertaining to apiculture, sufficient allowance should be made for the location and environments of the writer of an article as well as the hive he uses.

THE PLURAL-QUEEN SYSTEM OF DOUBTFUL VALUE IN DEEP HIVES.

Viewing the plural-queen system from the standpoint of the deep-frame hive, with its slow-going methods of manipulating frames singly, it is doubtful if it could be made a success. However, it should require little argument to prove to the bee-keeper of average intelligence the many advantages to be derived from the use of the plural-queen system when used in connection with the sectional hive with its improved methods of rapid hive manipulation.

Bee-keeping as a pursuit is progressing, and bee-keepers are fast realizing the necessity of employing short-cut, labor-saving methods. Twenty-five years ago rural electric lines, rural telephones, and rural mail delivery, were unknown. To-day the face of the country presents a network of electric and telephone lines, and every rural district has its free mail delivery; likewise the bee-keeper of to-day is compelled to meet greatly changed conditions. Good locations are scarce. Our one-time bee-pastures have given way to fields of waving grain, and the woodman's ax has laid low our forests of basswood. Our honey yield has been cut in two in the middle, which means that we must either adopt short-cut labor-saving methods that will enable us to keep twice as many bees as we kept before, or go out of business.

The bee-keeper of to-day who advocates the slow-going methods of a quarter of a century ago is fast becoming a back number. It is high time for this class of bee-keepers to wake up and take an inventory of stock before they get so far in the rear that they will never catch up.

As the horse-car has given way to electricity, so the old methods of handling, brushing, and interchanging brood-frames singly must soon give way to the more modern methods of rapid manipulation by hives.

Mr. Dadant's statement, that the queen is of vastly more value than any one thing connected with the colony, is literally true. Does not this prove that a plurality of queens increases the value of a colony? A queen may easily be worth ten dollars. Is not the bee-keeper making money who can rear such a queen at practically no expense, save for a very little time and with a little talent?

Again, Mr. Dadant discourses at considerable length upon the difficulties of rearing queens early enough in the spring to produce workers in time for the harvest. This argument falls to the ground in the face of the fact that queens are reared at the close of

harvest and carried over winter in shallow brood-cases. These little colonies, with vigorous young queens, will winter in a good cellar even better than a strong colony.

We have found it more profitable to work our bees on the two-queen system of swarm control, and then, at the close of the harvest, make our increase, as above stated, at a time when there is nothing for the bees to do, and every colony in the apiary can well spare enough bees, brood, and comb to stock one of these small brood-cases. By the above method each colony is provided with a young queen at the beginning of each season. When we consider that these queens are reared from our choicest breeders, it is easy to see the value of such a system as a means of improving our bees.

Two of the brood-cases, above mentioned, are equal in capacity to 8 L. frames; but we usually use three during the breeding season. At the close of the season, the third (or top) brood-case, with the young queen, is removed and wintered separately.

There are no weak colonies to nurse, and every colony in the apiary will be in condition to enter the sections at the beginning of harvest, and will give uniform results in honey production.

The claim that one queen will lay more eggs than a colony can care for, amounts to but little in the face of the fact that, if a weak colony is placed upon a strong one, the heat from the strong colony, and the addition of more nurses, will enable a weak colony to care for as much brood as the strong.

Again, the two-queen system is a guarantee against the loss of a crop of honey, which is often the result of the failure of the queen.

That the difficulty of introducing another queen is often used as an argument against the two-queen system is sufficient proof that the opponents of this system are not up to modern methods of rapid queen-introduction by hives.

All that is necessary is to place the small colony upon the strong one; only one cover is removed. It takes about a minute to do it, and not one queen in fifty will be lost.

If the colony added is very weak, a wire screen is used between the colonies until the brood-nest is well established, when the wire cloth is removed, allowing the bees free access to both brood-apartments through the perforated metal honey-board that separates the two colonies. It is merely two colonies under one cover and upon one bottom-board, which may be instantly separated whenever desired, and which insures a mighty army of workers for the harvest, and is practically a non-swarm. A medium colony usually amounts to but little.

If you want honey you must have a hive literally jammed with bees, and the two-queen system gets them without fail.

Birmingham, O.

[It is getting about time to close this discussion of the plural-queen system, as we do not believe it would be wise to prolong it much further at this time. Next fall or next

winter, after another season's work in testing it, we will reopen the question if desired.]

We may be warranted in drawing some conclusions as a result of the past discussion in these columns:

1. More than two queens to the hive is seldom necessary or desirable, and hence, in a general way, not practicable. The more the queens, the greater the complication.

2. The plural, or dual, plan ordinarily can not be worked, except by the use of queen-excluders, so that each queen can be kept from her rival, and that even then—

3. After the main or general honey-flow is over, one of the queens (or all but one) will be missing. This is not invariably so; but the general trend of the discussion seems to indicate that this is so with most of those who have tried it.

4. While the *plural* plan, as above noted, is not practicable, the *dual* (two queens to the hive) may be and probably is profitable under some conditions. The evidence thus far submitted seems to bear out this statement if we may believe the testimony of some good and competent men.

5. Not all hives or systems are adapted to the dual plan and we may say some men couldn't work it with any plan. Unless one has faith in this or *any* system there is not much use in his wasting time with it.

6. The dual plan requires more skill and patience to work it than the single-queen-to-the-hive plan.

7. The beginner had better let it alone until the veterans more generally are able to work it.

8. All veterans with the proper equipment should try it in a small way. The possibilities of the system seem too great to be lightly passed over.

We have attempted to take no sides in this discussion, but we have endeavored to have the subject thoroughly discussed and considered fairly before it was dropped.—Ed.]

DOG EAT DOG; SIC 'EM!

According to the latest newspaper reports, the Royal Baking Powder Co. intend to do things on a grand scale, and have invested \$1,500,000 in a glucose-factory at Roby, Ind. It is said the factory cost originally \$2,400,000. Had Dr. Wiley's decision on the glucose question been allowed to stand, it is safe to say the factory would have sold for much less. The Corn Products Co., we are informed, expected to buy this factory immediately after the decision, and are chagrined at the sale to others. Now, it is alleged, they have declared war to the knife, and intend to engage in the manufacture of baking-powder on a vast scale. They are well fitted to do this, as they have been supplying, or claiming to supply, the manufacturers of baking-powder with 85 per cent of their raw material. They use great quantities of soda to neutralize the hydrochloric acid in the manufacture of glucose, and, of course, this gives them a great opportunity to control the sale of it.

W. K. M.

LIQUEFYING HONEY IN CANS: WEIGHT OF STORES COMPARED WITH WEIGHT OF SUGAR FED.

A word about heating cans of honey. After the honey has begun to warm, loosen the screw cap with that corner of the can uppermost. This will let out the expanded air and gases. The cap can then be replaced, and later the act repeated if occasion demands. There is no danger of a can bursting from the swelling of the honey; but the expanding of much enclosed air or gas is quite likely to bring disaster.

If one has only a can or two to liquefy, let him try this plan: Lay the can on its side on the hot stove, turning it to expose a new side to the heat every two or three minutes. After the four sides of the can are fairly hot, set the can upright on a part of the stove where a kettle of water would keep hot but would not boil. The side heating loosens the cake of honey and causes it to fall to the bottom as the can is set upright. There is little danger of overheating so long as this cake of candied honey is constantly pressing down upon the bottom of the can. I find this a rapid way to liquefy, and a safe one when conducted properly.

On page 1508 Mr. O. S. Rexford writes of his experience in feeding winter stores. The editor asks for the experience of others. Mr. Rexford mentioned his experience in the fall meeting of our Connecticut Association. In consequence of that I experimented a little this fall. I was obliged to feed some fifty colonies for winter. In three cases I weighed the colony before and after the feeding, allowing two weeks for the syrup to become digested and stored in the combs. I found that the weight of stores was in each case from 15 to 20 per cent larger than the weight of the dry sugar used. The three colonies were simply fair selections from the fifty, and can be considered typical cases. Examination of the brood-nests of several others corroborated the result.

I feel sure that there was something unusual or abnormal in the case cited by Mr. Rexford. ALLEN LATHAM.

Norwich, Ct.

QUEENS REARED BY SWARMING IMPULSE TEND TO PERPETUATE EXCESSIVE SWARMING.

I think Mr. Alexander's statements on queen-rearing, Feb. 15, page 209, are well worth consideration. I formerly used swarm-cells altogether, with the result that every colony would almost invariably prepare to swarm, and some of the prime swarms would

swarm again in four weeks. Within the last few years I have reared my queens from colonies which do not swarm, and in colonies free from the swarming impulse; and the result is more than satisfactory, reducing swarming to a fraction less than four per cent. This conclusion might be questioned on the ground that the last two seasons were so very poor that colonies would not attempt to swarm much, or that the queens were poor ones and could not populate their hives sufficiently to swarm; but these bees produced an average of 62 pounds per colony in 1906, and about the same in 1907. Furthermore, the queens seem to keep their hives well populated throughout the season. The majority of the colonies which do prepare to swarm are those containing queens reared under the swarming impulse. I keep some of these for testing their prolificness and the honey-gathering qualities of their bees, and comparing them with queens reared on the supersedure impulse. I find these results are about the same.

J. C. ATKINSON.

Beaumont, O.

[Here is a statement on the other side of the question.—Ed.]

QUEENS FROM NATURAL-SWARM CELLS FOUND TO BE BETTER THAN ANY THAT WERE BOUGHT.

I have read Mr. Alexander's article, Feb. 15, page 209, about using queens from natural-swarm cells. Now, Mr. Editor, I have practiced that same thing for ten years, of course selecting the best cells or virgins from the best queens. I produce comb honey in ten-frame hives, and I use two hive-bodies until the beginning of the honey-flow. I find these natural-swarm-cell queens fill two ten-frame bodies with brood as readily as any queens I have been able to buy would fill a single eight-frame hive (I have bought queens from many queen-breeders, and have never been able to get one that would give me half the surplus the average swarm-cell queens do). I think continued selection along this line, instead of running a strain of bees out, as per Mr. Alexander, would in time give us the best it is possible to get by any possible plan or line of breeding.

Berthoud, Col.

A. C. VAN GALDER.

HOW TO TEST THE VALUE OF A QUEEN.

Mr. Editor:—In your comment on the article by Wm. M. Whitney, p. 36, Jan. 1, you ask how we can know a good queen the first season. This is an easy matter with me. It can be determined by putting a young queen, when she first begins to lay, on a ten-day test. Encourage her to lay by feeding the colony one pint of feed at night for ten days. Try this on six or more queens with the same amount of bees, and see the difference in the amount of eggs laid.

Little Rock, Ark. W. J. LITTLEFIELD.

[The laying test under stimulative feeding would determine only one thing, viz., her prolificness. She might be never so good in

this one respect, and yet fall down when her bees came to the honey-flow. Some strains of colonies, however populous, are inclined to loaf. By your test, a Holy Land queen ought to be a great honey-producer because she is a great layer. But an extended experience covering a period of years did not show that these bees were superior, if as good, in the production of honey as the less prolific Italians.

No, it will not take at least a season through to test a good queen, and it would take a year to give her an all-around test.—ED.]

CEMENT PAINT FOR OLD OR NEW HIVES.

Having studied your A B C very carefully for a year now, and from personal experience in painting hives for a year, and other outdoor farming implements for many years, I now use no more oil paints for hives, but the following recipe for this country, which is hot, is a perfect success so far as bees are concerned, and very much cheaper and easier than oil.

Take milk containing a large percentage of cream; add good cement slowly, stirring well until a good thick paint is made. Apply with a broad flat brush. Two or three coats put on will petrify the outside surface of the wood. I claim the following advantages for hives over oil paint: Cheapness, ease, and quickness of painting; cleanliness, no clothes or hands soiled; practically no swell; certainly not objectionable to bees; unaffected by damp or weather for years; fills up old cracks admirably; smooth surface; and last, but not least, a porous paint which does exclude air through the wood. The natural color is a yellowish slate; but any dry-powder paint may be added to give the desired color. I prefer the natural color, which always looks tidy and clean. One barrel of cement will or ought to do for hundreds of hives. It is necessary to paint occupied hives on a cool cloudy day, the idea being to keep the sun off for six hours, so that the paint will not set too quickly. The slower it sets, the harder the surface gets. Milk containing a good thick set of cream on top is much more preferable than skim or separator milk. It is also necessary to use up all paint mixed, within a few hours.

Amerspoort, So. Af. U. L. ROBERTSON.

HONEY-DEW GATHERED IN JANUARY.

I have seen bees gathering pollen here in January, but not before have I noticed honey coming in at this time of year. Jan. 22 was a very warm day, and I was not surprised to see bees flying out, but I could not understand why some of them alighted so heavily, just as they do in summer when a flow is on. There is a small patch of pines about 200 yards away, from which bees were busily coming and going—some of them so heavy that they dropped on the way. Upon examination I found a sweet liquid on pine twigs, which I took to be honey-dew. To make sure the bees were gathering this, I opened a hive that had a loose top, and found

a patch of brood near which I found several cells full of this liquid. This may be nothing new to some people, but it is something unusual to me.

HUGH JOHNSON.
Reidsville, N. C., Jan. 23.

A WET BOARD FOR WATERING BEES.

In watering bees in the spring of the year I place a board about 10 feet long and 10 or 12 inches wide on an incline, lengthwise. A bucket of water on the other end of the board, punctured at the bottom so the water will leak out and run down the board is just enough to keep the board wet.

I wet the surface of the board first, and the leak will usually keep the entire surface wet until the water has all run out. I teach my bees by being prompt to supply the water, so that they come regularly at a certain time. After they once start, it is surprising to see how many will get on the board in a short time.

B. J. WORSLEY.

Theresa, N. Y.

OUTDOOR FEEDING FOR STIMULATING.

For stimulative feeding I fill gallon jars with syrup, tie a cloth over the top just thick enough so the syrup will not run too fast, and turn the cloth end down on some short sticks so the bees can get under. If these are set in some nice warm place the bees work on it nicely, and it causes no disturbance. I use about 1½ to 2 lbs. of granulated sugar to each, for it also supplies them with the water they need.

What does any one want of two queenes if he can have queens like some I have, that fill two hive-bodies? One queen is enough for me; but I want good ones or none at all.

Mt. Jackson, Va.

S. CLICK.

SWEET CLOVER AS A FOOD FOR STOCK.

Last week, seeing in the cornfield sweet clover over two feet high in bloom I thought of a writer who said it would not grow in cultivated fields. The large plant which I send in a separate inclosure has grown from seed which has germinated since July 29, when the corn was last cultivated. I also send two young plants which have grown from seed since our first rain, Oct. 14. The whole field was plowed late last spring, and that part which is now covered with a dense growth of young clover, being above the irrigation line, was not planted. This part of the field was free from clover last year, and the seed must have lain dormant two years. I consider it a good plow-under crop. Today I counted over 100 nodules on one plant. This coming season I hope to save enough seed to plant ten acres, and the following spring plow it under for corn-planting. Last week I gave some sweet clover to a pen of young fattening hogs which had never eaten any. They were all very fond of it. Some horses and cattle do not relish it at first, but, like human being, have to acquire an appetite for some foods. I well remember my first attempt to eat an olive. Now you can scarcely feed me too many. If you have a

pet Jersey cow you wish to have love you, and give you a good quantity of rich milk, give her a good feed of sweet clover at milking time; but too heavy feeding with it will give the milk a peculiar flavor.

Descanso, Cal., Dec. 5. E. P. ST. JOHN.

OUR HOMES

by A. I. ROOT

And God blessed them, and God said unto them, Be fruitful, and multiply, and replenish the earth, and subdue it.—GEN. 1:28.

Please notice the above is what *God* said in the beginning of the human family. The very first command God ever gave to humanity was to be fruitful, and multiply; and a reason for it is given in almost the same breath, that we may *subdue* the earth. Just now in this year of 1908 we are subduing the earth in one sense, and may God be praised for it. But this Home paper is not to be a temperance talk, but rather a talk on "high-pressure gardening." Do you ask what our text has to do with gardening, etc.? Well, I think I can show you. A few days ago I saw in one of the Cleveland dailies a notice of the arrival of the first ear of Florida celery, and that it had sold readily for quite a good price. About the same time, Mr. Rood remarked that a man near us was offered \$5000 for his crop of celery, about ready to harvest, on only five acres of ground. As it was less than two miles from our home I sprang on my wheel and proceeded to investigate.

By the way, I do *once in a while* go back and "get astride" of my hobbies of former years. My wheel has only recently been shipped from the old "cabin home" (cabin in the woods No. 1), and I started off with my old enthusiasm for wheeling, and soon found that there is a "second wind" down here in Florida equal to any in the world. I was soon out in the wilderness, and had to inquire my way. Two colored boys and a white one were sawing wood.

Now, I want to stop right here to consider the *tremendous* difference in specimens of humanity. In this region I have been much impressed with the numbers of bright well-informed people. Yes, I have mentioned the good behavior and the well-educated condition of the colored people around here.

Now for my illustration: Not one of the three young men I met had ever *heard* of "Lattimer's celery-farm," while it was less than one-fourth mile from where they were at work. A fourth colored man, a little further along, told me to open the first big gate on the left-hand side and follow the well-traveled road and I would soon see the celery. The two photographs which will appear in the next issue of GLEANINGS will

give you a faint glimpse of the vision that suddenly burst on my (enraptured?) view. Let me explain a little.

At that time we were in the midst of a severe drouth. The morning was hot, and after I left the town there was little to be seen except the dry dusty wilderness. Every thing looked dead and dried up; and if you didn't *know* better you might be tempted to say none of the land was worth more than \$5.00 an acre. Well, imagine my surprise to see, all at once, a field of celery that eclipsed any thing I ever saw before in Florida or anywhere else.

A short time ago Manatee Co. cut a drainage-ditch through this locality that permitted draining a number of ponds, or swamps, and this was one of them. After the water was let off into the big ditch the next thing was to get water to put back on the ground during a dry time. As the garden was in a slight depression it was all spread out before me, as I stood on a little higher ground. I got a drink of water at one of the two artesian wells, and soon found a very bright young man of eighteen who regretted that his father, Mr. C. L. Lattimer, was just then away, but he kindly gave me the following points:

Mr. Lattimer, as nearly as I can remember, commenced work here in the woods just about a year ago last January, so that the wild land has been "subdued" (see text) and this wonderful crop grown in only a little over a year. Most astounding of all, the father had had no experience with celery before this time, and was not even an *experienced* gardener, and had had no experience in gardening or even farming in Florida.

As the boy gave me the facts I said:

"Why, my young friend, this is almost incredible. Your father must have suddenly developed a craze for celery-growing, and done a deal of studying."

"You can bet your life he did. We all of us studied it up, and we have just worked like beavers in clearing up the land and getting it ready."

"All of us?" How many children has your father?"

"Eight—four boys and four girls."

There you have it, friends. Mr. Lattimer has obeyed that first command that God gave humanity, and the loving Father has rewarded him.

Young Lattimer informed me further that such land can be bought for about \$50 or \$75 per acre, and that clearing it up and getting it ready for celery will cost about as much more. They have never yet used as much as a ton of fertilizer to the acre, costing about \$40 per ton.

The two artesian wells cost something like \$600 each. As nearly as I could gather, the entire outlay of cash has been *much less* than half of what he has been offered for the very first crop.

As fast as the celery is gathered and shipped tomatoes are put right on the ground, so the land is idle hardly a single day. The tomato-plants are grown in shaded beds

right on the premises, and were already growing finely when the celery had been sold off.

Now let me put in a word of caution. Mr. Lattimer was probably an excellent farmer in Alabama, where he came from. Before going into this venture he probably looked up celery-growing in this region very thoroughly, and I have reason to think he employs at least one or more expert men who know all about the business. I think, too, he must have ample means to do the right thing at the right time, for his son told me he had still another celery-ranch ten or twelve miles away.

Just now very good prices are being offered for *celery*; but during the past winter, I am told, carload after carload of *lettuce* has been grown that didn't pay cost. Mr. Lattimer had quite a little patch that was never cut, on account of the low price offered.

The bleaching is done with boards, and these are of what is called "pecky cypress." I do not know what the boards cost for an acre; but this kind of lumber can be bought here for about \$18 or \$20 per 1000. As it is light, never warps, and almost never rots, it is a splendid material for bee-hives. As the boards can be moved as fast as the celery is bleached sufficiently, and sold, only enough boards are needed at one time for a small part of the whole field.

Quite a quantity of water is needed during a dry time. As it lay in the furrow between the rows of plants it seemed to me it must be almost "knee-deep." The strong but not unpleasant perfume pervades the whole locality when marketing and shipping are going on.

SELLING SECRETS, ETC.

For some time past there has appeared in many of the poultry journals the following advertisement:

CUT OFF THREE-FOURTHS YOUR FEED-BILL.

Send us your name and address on a postal card, and we will send you free 16 sample pages of our revised book, "Successful Poultry Culture." This book will tell you how to actually make four bushels of the BEST FEED IN THE WORLD for chickens from one bushel of common grain, and it will tell you how to SAVE THREE-FOURTHS YOUR FEED-BILL.

This is certainly the greatest discovery of the 20th century, and will *double and triple your profits* in the poultry business. These 16 sample pages are absolutely free, and will tell you all about it. Send us a postal to-day for them.

RECORDER PUBLISHING CO.,
332 Dearborn St., Chicago, Ill.

A cut, which we do not reproduce, represents a loaf of bread cut in four pieces. I suppose the advertiser does not object to our giving him one insertion of this advertisement free of charge. Now, the greatest obstacle in the way of successful poultry-keeping in Florida is the cost of grain; and it certainly would be a big item to be able to save *three-fourths* of this expense. I accordingly sent at once for the free (?) sample pages that the above advertisement says will "act-

ually tell you how to make," etc. The 16 pages came promptly; but they did *not* tell the wonderful secret. They simply indicated that it was given in *one* chapter of the whole book, and you could not get the whole book unless you sent them \$1.00 for it. If they make misstatements in their advertisement, why should they not make more in their dollar book? But as I had started in to save three-fourths of my grain I thought I would follow the thing out. I found, as I rather suspected, it was the Briggs secret of making "feed for ten cents a bushel" that I exposed and wrote up at different times during last year*. As I have been feeding sprouted oats and also sprouted corn and wheat all winter, more or less, I ought to know something about it. While sprouted grains are excellent feed for fowls, especially during the winter time, when there is apt to be a dearth of green food, I am satisfied that you *do not* cut off three-fourths of your feed-bill, nor any thing like it. May be the sprouted grain will go *twice* as far, but I very much doubt that. It seems to me our experiment stations are the ones to settle this matter before more such statements come out along this line. Poultry of all ages will eat with avidity sprouted grain, even when the sprouts are as much as six inches long. I suppose all of you have seen fowls scratch up seeds in the garden, and then swallow them, and the plant attached, with great satisfaction, and no doubt this is an excellent thing for poultry; but will our experiment stations please tell us how *much* money it saves in feeding sprouted corn and oats instead of feeding the grain itself? If the advertisers are right in saying that one bushel furnishes as much nutriment as four bushels of dry grain, I will beg their pardon and be glad that I have advertised for them.

Sprouted grains, as is well known, have been used more or less for human food. In the Chinese quarters of San Francisco, and in some other cities, I have seen sprouted peas offered for sale in front of the Chinese groceries. "Malted nuts" are excellent food, and, I believe, are made from nuts that have been sprouted so as to convert the starch into sugar for making a more delicious food, and perhaps a more digestible one. But if one bushel of sprouted oats is worth as much as three dry for poultry, why wouldn't they be worth something for horses or for human beings? I have often gathered beechnuts in the woods in the spring of the year, when the nuts had sprouted till the plants were two or three inches high, and they were very good food.

Now, then, who will tell us more about sprouting nuts and grain for human food? And, by the way, why do not some of our enterprising poultry journals inquire into such things a little more before inserting advertisements like the above?

*The "book" is a cheap paper pamphlet, 128 pages, with nothing in it particularly new or valuable except about two pages on sprouted grains.

"Seaboard Magazine" ^{SIX} SOUTHERN STATES ^{Sent} EABOARD'S TRONCHOLD ^{Free} A MAN'S DISPOSITION

is, without doubt, seriously affected by the climatic conditions which surround him.

ARE YOU PLEASANTLY LOCATED?

Are you shut in by the ice and snow of a rigorous winter, with naught but a cheerless sky to gaze upon? What of your lands now? Covered with snow? How about your stock? Have to be kept housed and fed?

The farmers in our territory are plowing, their stock grazing on the hillsides, and in the famous Manatee section growers are shipping their products to Northern markets, receiving remarkable prices for the same, due to the season.

Our lands are just as fertile as yours, produce just as much and at a time when prices are the best. It's a duty you owe yourself and family to look into this.

CLIMATE IS A MOST IMPORTANT FACTOR in connection with the profits, as well as pleasure, to be derived from your location.

Wouldn't you like to be pleasantly situated, surrounded by climatic conditions which permit work to be carried on the entire year, and where the struggle for existence against the elements of a frozen North is not known?

The climate in the six States traversed by our line is unsurpassed anywhere, and the profits being derived by those who only a few years ago were battling with the rigors of winter in a northern location is evidence of the value of our lands. Do you expect to remain where you are and keep up the struggle? Why not come down into southern sunshine and be pleasantly located, while at the same time you are deriving big profits from your crops?

OUR LITERATURE IS FREE. The "Seaboard Magazine," prepared especially for the benefit of parties contemplating a change of location, will help you. Let us put your name on our mailing-list. Drop us a postal to-day,

J. W. White,
General Industrial Agent,
Seaboard Air Line Railway,
Dept. F, Portsmouth, Virginia.

FREE! 50 lbs. Comb Foundation FREE!

WEED'S NEW-PROCESS COMB FOUNDATION.

PRIZES GIVEN AWAY

ABSOLUTELY FREE IN A CONTEST.

FIRST PRIZE—25 lbs. Comb Fdn.

SECOND " —10 lbs. Comb Fdn.

THIRD PRIZE —5 lbs. Comb Fdn.

FOURTH " —5 lbs. Comb Fdn.

FIFTH PRIZE—5 lbs. Comb Fdn.

THE ABOVE PRIZES will be given absolutely free to those who will make the largest number of words out of the letters found in the name "Toepperwein." The letters may be used over as many times as desired, but in no single word oftener than found in the name "Toepperwein." Only words found in Webster's dictionary are admitted. The words must all be plainly written in columns, and numbered.

This contest is absolutely free to any one and anywhere. It is a fair contest, and one has the same chance as the other. These contests are very instructive, and just the thing for schoolchildren to pass the evenings. The contest will close May 1, 1908, and all lists with words must then be in, and in May 15th GLEANINGS the results will be published, giving the names of the winners and all the words of the one who wins the first prize. The winners have the privilege of choosing any grade of foundation. We feel confident that the winners will be highly pleased with the prizes, as the comb foundation is as fine and perfect as any machinery can make, and is made right here in our factory out of this clear Southern beeswax.

13,000 CASES OF HONEY-CANS

on the way which will be here in time to supply the bee-keepers with cans. We buy honey in large amounts at market price.

Whenever you are in San Antonio make our office your headquarters and let us show you through our plant. Stay here a while and meet the bee-keepers as they come in. You are always welcome and will be courteously treated.

UDO & MAX TOEPPERWEIN,
1322 South Flores St. SAN ANTONIO, TEXAS.

ITALIAN Queens

and bees, and nothing but Italians. An improved superior strain is what QUIRIN-THE-QUEEN-BREEDER raises. Our stock is northern-bred and hardy. We just visited our outyards (all wintered on summer stands), and not a colony is dead to date (March 18). Some hives have lost scarcely a bee, so it appears. BROTHER BEE-KEEPER, how do you like such stock for hardiness? A party up in Maine got 50 nuclei of us several years ago. We just received a letter from him. He is after more of our bees, because last season he got 2200 pounds of honey which sold for 22 cts. per pound. Our stock is well known throughout the United States. Some of the largest yields reported can be traced to our stock. Over 20 years a breeder. Free circular and testimonials. Price of stock as below.

Prices of Queens before July.	1	6	12
Select queens	\$1 00	\$5 00	\$9 00
Tested queens	1 50	8 00	15 00
Select tested queens	2 00	10 00	18 00
Breeders	4 00		
Golden five-band breeders	6 00		
Two-comb nuclei, no queen	2 50	14 00	25 00
Three-comb nuclei, no queen	3 50	20 00	35 00
Full colonies on eight frames	6 00	30 00	

ADD the price of whatever grade of queen is wanted, with nuclei or colonies; nuclei ready about May 1st to 10th; can furnish bees on Danzenbaker or L. frames; pure mating and safe arrival guaranteed. We employ 400 to 500 swarms in queen-rearing, and expect to keep 500 to 1000 queens on hand ready to mail. Our Northern-bred bees are hardy, yet gentle; they will give you results. Address all orders to

QUIRIN-THE-QUEEN-BREEDER, Bellevue, Ohio

Imported Carniolans, Caucasians, Queens

and Hungarians (Banats), each bred in native land of respective race, \$5.00 each. Now on hand ready for immediate delivery.

The Time To Place Your Order for **QUEENS**

for spring delivery is here. Order now (with partial payment if not convenient to send all) and state when you want delivery. When ready for the queens, send the remainder. By so doing I shall be able to handle your order without the usual delays incident to the rush orders when the season is on.

	1.	6.	12.
Untested, in May and June, \$1.00	\$5.50	\$10.00	
Untested, after July 1	.75	4.00	7.50

Selects, 25 cents extra. Tested, May and June, \$1.50; after July 1, \$1.25. Nuclei and full colonies ready May 1. Catalog for 1908 free. Send for one.

GEO. W. BARNES, Box 340, NORWALK, O.

Westwood Red-clover Queens

Are the bees that got the honey in 1907. Better try them for 1908. Nuclei and full colonies a specialty. Price list on application.

HENRY SHAFFER, 2860 Harrison Ave., Sta. L, Cincinnati, O.

PHARR'S GOLDENS

took first prize at three exhibits in 1907. We also breed Carniolans, three-banded Italians, and Caucasians, bred in separate yards and from the best breeders obtainable; guarantee safe delivery and fair treatment. Untested, \$1; tested, \$1.25. Address **New Century Queen-rearing Co., Berclair, Tex. John W. Pharr, Prop.**

W. H. Laws is again on hand for the coming season with a larger stock of queens than ever before. He sold 400 queens to a New Mexico producer last May who wrote, "Your stock is far ahead of those Eastern queens I have been buying," and has placed his order for 1000 more of the Law queens to be delivered in May and June coming.

Others write that, if they had purchased all Laws queens, their crop of honey would have been doubled. Testimonials enough to fill this book. If you are going to improve your stock, had you not better investigate?

Single queen, \$1.00; dozen, \$10.00; breeders, the best, each, \$5.00. **W. H. LAWS, Beeville, Bee Co., Texas.**

Queens Queens

of the

FINEST POSSIBLE BREEDING

BRED BY

F. J. WARDELL,
UHRICHSVILLE, OHIO, U. S. A.

After many years' experience as head queen-breeder for The A. I. Root Co. I am now breeding bees at the above address. My stock is equal to any now advertised, and my long experience enables me to judge very accurately the value of any strain. Mine is the celebrated red-clover stock, which has given so much satisfaction to thousands of buyers for a number of years past. If you desire something very select for breeding purposes, write to me, stating your wants, and the same will be supplied. I have no cheap or inferior queens to sell. My prices for the season are as follows:

	May to June.
Untested queen	\$1.25
Select untested queen	1.50
Tested queen	2.50
Select tested queen	3.50
Breeding queens	6.00
Select breeding queens	9.00
Extra select	1 year old, 12.00

No untested queens sent before May 15; but to secure your queens early in the season it is necessary to order now. Absolutely, all orders filled in rotation.

We are READY NOW to take your orders for Bees—Nuclei and Queens

Shipment can be made with safety on and after May 15; we guarantee safe arrival then. If you want queens early, communicate with us; we have a few that we can ship by May 5, at your risk.

Don't forget that we do a general bee and honey business; that we can supply you with Root hives and fittings, sections, foundation, tools, etc., at their factory prices. It is not necessary to have our catalog (though we send it free); make your list from any Root catalog published this year; send us the total amount, and we'll ship the goods by the most direct route. Dozens of freight trains enter and leave Bangor each day, and we're waiting to hustle your order aboard one of them in red-hot fashion. If you're not decided about some detail, or want us to quote you a net price on the supplies you want, write us; the mails travel 800 miles a day, and you will be surprised to see how quickly we will answer your inquiries. And we'll do it cheerfully too.

SEND US YOUR WAX. We are giving thirty cents cash, or thirty-three cents in trade for pure yellow beeswax of average quality.

TIME IS UP on our special book-offer May 1. After that date all bee-books and journals will be sold at regular price instead of the 10 per cent discount we have been giving.

GEO. S. GRAFFAM & BRO., Fifth St., Bangor, Me.

How are Your Bees?

Any Queenless Colonies?

If so, send for a queen at once. We can furnish by return mail fine tested queens, reared last fall, wintered in four-frame nuclei, three-banded Italians, none better, \$1.00 each. Satisfaction guaranteed. Send for price list.

J. W. K. SHAW & CO.,
Iberia Parish, Loreauville, La.

TO INTRODUCE OUR NEW WALL-CHARTS

These charts are a splendid compilation of facts, figures,
and drawings, showing all the latest statistics gathered by the
county and State officials. They are of wonderful value in the
home and in all classes of business. Railroads are shown up-
to-date, special attention being given to them. All counties,
towns, and postoffices fully indexed, and population given;
many other features too numerous to mention. A splendid
opportunity for energetic men.

for price. Michigan White-Clover Honey Co., Detroit, Mich.

FOR SALE.—It will pay to get our special proposition.
A. G. WOODMAN & CO., Grand Rapids, Mich.

The Hand System

TO satisfy a number of customers we are now making hives to suit the above system, just as the inventor him-
self uses them. These are not listed in our regular spring catalog, and are not kept in stock at any of our
agencies. All orders will be filled from Medina. If ordered early enough, however, they can be forwarded to
any one of our branches for redistribution. If you are going to try a few of these hives the coming season, we
earnestly urge you to order early before the rush season comes on.

PRICE LIST OF HAND DIVISIONAL HIVE AND PARTS.

We have had numerous calls for divisional hives just as Mr. Hand uses them. We will not list them
in our catalog for the coming season, but will make them up to supply on special order, to those who
desire to try them, at prices in table below. The outside dimensions being nearly the same as the reg-
ular Dovetailed hive, the regular covers and bottoms may be used.

Each section is 19½ in. long, 5½ in. deep outside; upper por- tion of side removable with clamps to hold it in place. Sections used are 4¼x4¼x1½ plain, split three sides. Furnished in both eight and ten frame size.	Designating or Short Name	Nailed and Painted Each	In Flat

Send for illustrated catalog and prices. Address W. F. & JNO. BARNES CO., 545 Ruby Street, ROCKFORD, ILLINOIS.

HONEY WANTED.

We are in the market for comb honey in Danzenbaker sections, either clover or basswood. Only fancy or A No. 1 grades are required. If you have any on hand which meets these requirements, please communicate at once, stating quantity and price.

CARTONS FOR OUNCE CAKES OF BEESWAX.

We can supply cartons for one-ounce cakes of beeswax, printed with name and address blank, at 35 cts. per 100; 250 for 80 cts.; 500 for \$1.50; 1000 for \$2.75; by mail, 15 cts. per 100 extra. These prices will also include the large carton to contain 32 of the small ones. The complete package weighs 2 lbs., and, when filled, sells to the dealer at \$1.00. They retail the cakes at 5 cts. each. Retinned molds for molding ounce cakes cost 35 cts. per dozen; by mail, 40 cts.; for two-ounce cakes, 40 cts.; by mail, 50. We do not have cartons to fit the two-ounce cakes. To print your name and address on the cartons will add, 250 or less, 50 cts.; 500, 75 cts.; 1000, \$1.00.

THE ALEXANDER BEE-VEIL.

We have secured, for making a bee-veil of wire cloth, a special weave of cloth having 8 meshes to the inch, and No. 32 wire painted black. Ordinary window-screen cloth is of the same size of wire, and 12 to 14 meshes to the inch. This special cloth is, therefore, more transparent, and obstructs the vision less than any other cloth we were ever able to secure. One objection to a veil of this kind is its bulk and the difficulty of transporting it, either by mail or when packed with other goods. We have overcome this one objection by making it with an open seam from the crown to the bottom of the skirt. Eight small safety-pins are included to pin up this seam when you receive it, or you may prefer to sew it up. The veil is rolled up so as to be placed in a box 3 x 3 x 12 inches so that it can be mailed safely for 12 cts. postage, or packed with other goods to go by freight. Price, complete, 60 cts. By mail, 72 cts. Special wire cloth for veil furnished at 6 cts. per foot or piece for a veil at 18 cts.; by mail, 3 cts. a foot extra, or 25 cts. postpaid for a veil-piece 10 x 33 inches, having edges folded ready to sew on the cloth parts.

SIMPLEX HONEY-JARS.

The factory have assured us that we may again secure this popular honey-jar in several sizes, including the one holding one pound of honey. We have ordered a fresh supply, and expect to have them in stock this next month. They will be packed in reshipping-cases of two dozen each, and the price will be \$1.10 per case; 6 cases, \$6.30.

NO. 25 HONEY-JARS.

During the past year we have had an unusual amount of trouble with breakage of this jar, even in the reshipping-cases packed with corrugated paper. The breakage occurred either in the porcelain cap or the top rim of the jar where the cap rests. We find we can get this same jar with lacquered tin cap without the center being cut out. This cap is lined with waxed paper wad, which seals tight on the top edge of the jar. This style of cap not only does away with breakage almost entirely, but enables us to furnish the jar at a

lower price. We are not yet supplied with the new stock, but expect to have them this month at the following price. They will be packed as usual, two dozen in reshipping partitioned cases. No. 25 jars, tin cap lined, 90 cts. per case; 6 cases, \$5.10. We can still furnish from stock the usual style of No. 25 with porcelain caps at \$1.10 per case; 6 cases, \$6.30.

MAPLE SYRUP.

We have a good supply of very choice maple syrup which we can supply at \$1.00 per gal.; 6 gal. at 95c; 20 gal. or over, 90c. Will be pleased to hear from those interested. Maple sugar is not so plentiful, and we can not offer this at less than 15c per lb. for best; 13c for fair to choice.

Special Notices by A. I. Root.

WANTED—SEEDS OF HONEY-PLANTS.

Just now we are sold out of both spider plant and figwort (or Simpson honey-plant). If any of our readers have any seed of the above-named plants that they have saved, and will mail it to us, we shall be very glad to allow them what it is worth.

BASSWOOD-TREES FOR SPRING PLANTING.

I find on my return home from Florida that our people are sold out on basswoods "one foot and under." We are also sold out on every thing more than about 3 ft. high. But we have quite a good supply of little trees from 1 to 3 ft. high. Prices will be, for one tree, 10 cts.; 10 for 50 cts.; 100, \$4.00. These are rather big to send by mail. But we can, however, pick out the smallest ones so the postage will not be so much, and send you ten of these little trees by mail for 50 cts. Better get in your orders at once if you want them, as they will soon be budding out; and they do much better when taken out of the ground before the leaves have made very much of a start.

ANOTHER POULTRY-BOOK.

On p. 527 a new book on poultry is announced; and as some of the claims made for it sound a little extravagant I sent for it while I was in Florida, and read it through twice, and certain parts of it several times. The book is so much in the line of my "nature studies" with poultry during the past two winters that I wrote to the author I should like to make him a visit; and I have to-day, April 9, just returned from that visit. I am satisfied that Mr. Philo has struck on a plan of saving a greater part (and perhaps almost all) of the chickens that die in the shell, even with the best incubators. I am satisfied, too, that he is succeeding with a fireless brooder, even during the winter months. I saw them not only at his place, but at several other places, working with apparent success. His plan of keeping poultry permits them to be kept, even in a crowded town or city, without annoying the neighbors. He seems also to have demonstrated that he gets fully as many eggs by keeping a few hens, say half a dozen, in the little houses he has devised, as where they have unlimited liberty. It is true the book is not a very large one; but the price, \$1.00, includes a year's subscription to the excellent *Poultry Review*. When I first got the book, when I was down in Florida, I sat down and wrote the author as follows:

Friend Philo:—I have had your book three days, and have read it through twice and much of it three or four times. The book is all original. Not only every page but almost every line has the stamp of a real practical worker, and of a deliver for nature's secrets. It strikes on a hundred points where I have been pushing ahead in the dark—yes, in the dark, for the reason that the multitude of poultry books and journals have scarcely a word to say in the way of helping the explorer; and you have also done more than any other poultry writer, so far as I know, in making chickens attractive, and their care easy for the average boy or girl in towns and cities where room is expensive. The same will apply to poultry for elderly men and women.

Bradentown, Fla., March 10.

A. I. ROOT.

After looking it over more or less during the past month, and finally paying him a visit, I see no particular reason to change my mind in regard to the book as a system of poultry-keeping.

We expect to give a picture of one of his little poultry-houses in our next issue; and I shall then have something more to say in regard to my visit to his place.

Convention Notices.

Mr. Root:—In the notice sent to GLEANINGS, and published in the March 15th and April 1st issues, the date for the meeting of the Central Tennessee Bee-keepers' Association was given as April 25, when it should have been March. The meeting took place on March 28, and I am enclosing a report of same.

The Central Tennessee Bee-keepers' Association met at the rooms of the Nashville Board of Trade on March 28, with about twenty members present.

Mr. J. M. Davis read a paper entitled "The Advantages of Associations;" Dr. J. L. Butterworth gave a description and demonstration of the Danzenbaker hive, and the following subjects were presented in an interesting manner: "Moving Bee," by Mr. G. N. McKannon; "Transferring," by Mr. Leslie Martin; "Comb Honey," by J. M. Buchanan.

The old officers were unanimously elected for another year—J. M. Davis, Spring Hill, President; W. M. Joseph, Nashville, Vice-president; J. M. Buchanan, Franklin, Secretary.

It was decided that this Association join the National Bee-keepers' Association in a body.

The date for the regular annual meeting was fixed for the second Saturday in March of each year, after which the association adjourned to meet August 8, at 10 A.M.

J. M. BUCHANAN, Sec.

Franklin, Tenn.

WHAT SHALL BE DONE AT THE NEXT NATIONAL CONVENTION?

We have laid the foundations for the next National convention. We have selected the city (Detroit) in which it is to be held, secured the Wayne Sun Parlor for holding the meeting, and decided on the dates—Oct. 13, 14, 15. We know where and when the convention is to be held, and can begin to lay our plans accordingly.

The next step is the arrangement of a program. Of course, the burden of this work will fall upon the secretary; but he can be greatly assisted, and the convention made vastly better by the help, hints, and suggestions of the members. It is with this end in view that I am going to outline briefly what I have in my own mind; then, as is the case at a convention when a motion is made, we shall have something "to talk to."

I would suggest that the first session he held in the evening, and wholly devoted to a discussion of diseases of bees. I have made application to the authorities at Washington to send a scientist to the meeting, probably Professor White, who can take up the matter from a scientific standpoint, show how these diseases are studied by the use of cultures and illustrate the matter with a stereopticon if possible. Then have some one of the inspectors tell how a practical bee-keeper can detect foul brood. He, too, might use stereopticon pictures in giving his description. Ernest R. Root has promised to furnish the stereopticon, if one is desired. Next, let another inspector give the best methods of treating diseases. Then wind up the evening by a general discussion of the subject.

Another feature that has been suggested to me is that of having at least one *debate* during each of the day sessions. I believe this is something that has never been attempted at any of the meetings of the National. Suppose, for instance, we take up the size of hives. Let us say: "*Resolved*, That a twelve-frame Langstroth hive-body is more desirable, in the production of extracted honey, than an eight-frame hive-body." Get some experienced, competent man to take the affirmative, and some other equally good man, who believes in the eight-frame hive, to take the negative. Let these men be chosen early in the season, secure their consent thus to enter the arena, then they can have months to prepare for the contest, and we common folks can sit back and enjoy the "feast of reason and the flow of soul."

As a rule, I think that most of our conventions are held down too closely to the steady grind of hard discussion, session after session, from beginning to end of the meeting. I think at least one evening session might be very profitably and pleasantly devoted to something in a lighter vein. I suppose that a banquet followed by responses to toasts would be in this line, but there are objections. First is the cost, which would not be less than \$1.00 a plate. This is not really serious, although there might be some difficulty in determining in advance how many would participate, so that preparations might be made on a

sufficient scale. I may be old-fashioned; but the real objection, in my mind is the late hour at which we would be compelled to begin our responses. The regular supper would have to be out of the way before the dining-room could be used for spreading the banquet, which would require some little time. If we finished our feast at half-past nine we should be fortunate indeed, and it is likely that midnight would still find most of us out of our beds. To persons accustomed to late hours this would mean nothing; but most of us bee-keepers are plain country folks, accustomed to early hours; and to be up half the night means extreme dullness—possibly a headache the next day. To attend a convention at some distance from home is more or less of a strain at best, and every precaution ought to be taken to see that the members feel just as well and as bright as they possibly can, otherwise there is but little enjoyment. My idea is that we cut out the banquet part—the feast at nine or ten o'clock at night. Just take our usual supper at the usual time, then meet at the usual time, 7:30, or whatever time we think best, and begin at once the responses to toasts or sentiments, finishing up at nine or ten o'clock, then the next day we shall feel as well as ever, ready for business and discussions, and able to enjoy ourselves. I would suggest that eight or ten of our best speakers be chosen, and appropriate topics be selected for each, early in the season, so that there may be plenty of time for preparation and thought. I would announce the topics in advance, also the list of speakers; but I think I would leave it a secret as to which speaker any given topic would be assigned, until the announcement is made by the toastmaster. I think the speeches ought not to exceed ten or fifteen minutes. The right man can say a lot of good things in fifteen minutes.

Another feature, for which I shall put forth my best efforts, is to secure the greatest possible attendance of bee-keepers' wives. It may be just a little out of the line of bee-keeping, but I hope I may be pardoned for saying that, naturally, business takes men out into the world. A man has the incalculable advantage of a great variety of experiences and freshness of view. He is continually coming in contact with new people, new things, and being molded by a vast number of forces which never touch the wife in the quiet home. I believe most women feel this terrible depression of the monotony of their lives, the lack of that stimulus which comes to man from constant change. Let us begin now to plan for the making of a big break in that monotony next October. There is a saying that good works and charity ought to begin at home, so I have secured a promise from Mrs. Hutchinson that she will accompany me to the convention next October. Then I secured a similar promise from my brother's wife. Then I wrote to a few near acquaintances, such as Manager France, President Hilton, Ex-president Aspinwall, and asked them if they would bring their wives, and all replied that they would do so. My friend Muth, of Cincinnati, also writes me that he will bring Mrs. Muth.

I think I would have at least one good essay each session, then the debate, as already mentioned, and finish up with the question-box, which I hope will be contributed to from all over the country by those who are so unfortunate as to be unable to attend.

One other little point: As every thing promises to be on a larger scale than usual, I have already made arrangements for the use of a camera that will take a picture 14 x 17 inches, and I hope to make a group picture that every member will be proud to hang upon the walls of his home. I shall see to it that each person in the group has a number upon the lapel of the coat; and a printed list giving numbers, names, and addresses, will accompany each picture, then all can see who is who.

What I have written gives simply a glimpse of the program in embryo. Nothing is definitely settled. I shall do my utmost to make the convention one of the most enjoyable, the best and most really helpful, that the Association has ever held; and I earnestly request every one who has any interest whatever in the matter to write me a letter full of advice and suggestions. Tell the subjects you would like to have discussed, and the persons you would like to have responses to, and the men you would desire to hear respond. Tell me what subjects you would like to hear debated, and the men you would like to hear do the arguing. If I have suggested something that does not please you, let me know, giving reasons why. Take hold right now, and do your share in making the coming convention a grand success.

W. Z. HUTCHINSON, Sec. N. B. K. A.

Mr. Bee-keeper, ☐

Was 1907 a POOR YEAR for you?

It was a GOOD YEAR for users of

DADANTS' FOUNDATION.

One dealer used 14 000 pounds.

Another dealer used 7,250 pounds. Another dealer used 4 500 pounds. Another dealer used 4,500 pounds.
Another dealer used 6,000 pounds. Another dealer used 4,500 pounds. Another dealer used 3,000 pounds.

Thousands of pounds sold to the bee-keeper direct, or worked up for him out of his beeswax.

The DEALER likes DADANT'S FOUNDATION because the bee-keeper likes it.

The bee-keeper likes it because his BEES like it.

The BEES like it because it is exactly like their own comb, so PURE and SWEET and CLEAN.

DADANT'S FOUNDATION is the Standard because it is the BEST.

Wax worked into foundation.

ARE THEY WORTH SAVING?

Mr. Haviland Saves 28 Chicks in One Hatch.

Fully one-third of all the chickens ready to hatch die in the shell. After 30 years' study and practice we have discovered a simple way to save every chick that is fully developed and ready to hatch, whether the egg is pipped or not. This, we believe, is one of the lost arts of the ancient Egyptians. It takes but a minute to save a chick, and no skill required. Note Mr. Haviland's success:

Dear Sirs:—
I received my copy of the Philo System at noon, the last

Brookville, Md., Feb. 27, 1908

hour of the 21st day for my incubator, containing 172 fertile eggs. About 100 were out of the shell and about 30 of the remainder were still alive, some pipped. According to directions with our hot-air machine these were worthless. We immediately proceeded according to "A Trick of the Trade" in your book and hatched them all, even one that showed signs of life after laying in a garbage-pail for some time. We still have 128 chicks three days old; lost but two. Many of the eggs were three or four weeks old when set.

Respectfully,

E. W. HAVILAND.

\$200 IN SIX MONTHS FROM 20 HENS

To the average poultryman that would seem impossible, and when we tell you that we have actually done a \$500.00 poultry business with 20 hens on a corner in the city garden, 30 feet wide by 40 ft. long, we are simply stating facts. It would not be possible to get such returns by any of the systems of poultry-keeping recommended and practiced by the American people, still it is an easy matter when the new PHILO SYSTEM is adopted.

The Philo System is Unlike all other Ways of Keeping Poultry

and in many respects is just the reverse, accomplishing things in poultry work that have always been considered impossible, and getting unheard-of results that are hard to believe without seeing; however, the facts remain the same and we can prove to you every word of the above statement.

The New System Covers all Branches of the Work Necessary for Success

from selecting the breeders to marketing the product. It tells how to get eggs that will hatch, how to hatch nearly every egg, and how to raise nearly all the chicks hatched. It gives complete plans in detail how to make every thing necessary to run the business, and at less than half the cost required to handle the poultry business in any other manner. There is nothing complicated about the work, and any man or woman that can handle a saw and hammer can do the work.

Two-pound Broilers in Eight Weeks

are raised in a space of less than a square foot to the broiler without any loss, and the broilers are of the very best quality, bringing here three cents per pound above the highest market price.

Our Six Months' Old Pullets are Laying at the Rate of 24 Eggs Each Per Month

in a space of two square feet for each. No green cut bone of any description is fed, and the food used is inexpensive as compared with food others are using.

Our new book, the Philo System of Progressive Poultry Keeping, gives full particulars regarding these wonderful discoveries with simple, easy-to-understand directions that

are right to the point, and 15 pages of illustrations showing all branches of the work from start to finish.

Our New Brooder Saves Two Cents on Each Chicken

No lamp required. No danger of chilling overheating, or burning up the chickens as with brooders using lamps or any kind of fire. They also keep all lice off the chickens automatically, or kill any that may be on when placed in the brooder. Our book gives full plans and the right to make and use them. One can be easily made in an hour at a cost of 25 to 50 cents.

Dear Sir:—
I am well pleased with your system in poultry-keeping. We have more than doubled our egg production.

Yours truly,

J. C. THAYER.

Gentlemen:—
Some time ago I ordered your book, Philo System, and your paper. Want to say I am highly pleased with them. Never in my life have I received so much for so little money. It is a very comprehensive treatise indeed. Your methods are so simple that a child might follow them.

Yours truly,

J. BERT MCCONNELL

Gentlemen:—
Your publication, the Philo System, at hand and, after careful comparison, must say that without doubt or hesitation that more boiled-down, good common sense and natural facts and instruction are condensed in the pages of your book than in all I have tried (to learn) and read the date.

Yours with best wishes, GEO. A. WOLFF.

Dear Sir:—
Your book came to hand and I must say I am very much pleased with it. It is far the best book I have seen on poultry. The ideas set forth in the book, which are the results of your experimentation, certainly show that you are a little in advance of others in this work.

Common Era, Ill., March 19, 1908.

I have built several of the brooders as described by Mr. Philo, and at present time have young chicks, a week old, outdoors, healthy and strong, without being warmed by any artificial heat.

Yours respectfully, WILSON BROOKS.

SPECIAL INTRODUCTION OFFER. We will send the book and right to use all patents and one year's subscription to Poultry Review for \$1.00.

POULTRY REVIEW, 23 Third Street, ELMIRA, NEW YORK.

SHELTER FROM SUN OR STORM

There's a certain satisfaction in owning a "Sheltertop" Buggy that no other buggy can supply. Why? When you start out for a drive, or on a long business trip, you know for a certainty that it's going to be pleasant. In hot weather the "Sheltertop" protects you from the sun's sweltering rays. If a storm or a sudden squall comes up, simply close the buggy and ride dry and comfortable. No ifs or ands or maybes about it—you cannot forget to take along the side curtains, or the storm front, because they are a part of the "Sheltertop"—out of sight when not in use—handy to get in position when needed.

THE "SHELTERTOP" BUGGY

THE
ONE BUGGY
FOR ALL
WEATHERS

Three simple one-hand movements—done in three seconds—without leaving seat, stopping the horse or dropping the lines, shuts the "Sheltertop" up so tight a drop of water cannot get inside the buggy no matter how hard it rains or the wind blows. Changed instantly from a handsome, fair-weather buggy to a cosy shelter from wind, rain, dust and mud. The only real improvement in buggies since the days of the Deacon's Old One-Horse Shay. Constructed from the best materials money can buy, in a factory especially equipped with the latest machinery, by skilled buggy builders. Handsomely finished, and sold on **30 days' free trial** before you pay us a cent. We ship the buggy and allow you to try it—we want you to use it just as if it were yours—we want you to ride in it in all kinds of weather, and convince yourself that it is the buggy to buy. While

you are buying a buggy you might as well get the best. The protection you can get only in the "Sheltertop" Buggy alone is worth every dollar the buggy costs. Write to-day for catalog describing the construction of all parts of the vehicle, and be sure to ask for our **free trial plan**. Don't buy a buggy until you get the catalog and this information. Yours truly, J. C. THAYER.

Gentlemen:— Ligonier, Ind., Jan. 24, 1908.
Some time ago I ordered your book, Philo System, and your paper. Want to say I am highly pleased with them. Never in my life have I received so much for so little money. It is a very comprehensive treatise indeed. Your methods are so simple that a child might follow them.

Yours truly, J. BERT MCCONNELL.

Gentlemen:— R. F. D. 1, Melrose Park, Ill.
Your publication, the Philo System, at hand, and after careful comparison, must say that without doubt or hesitation that more boiled-down, good common sense and natural facts and instruction are condensed in the pages of your book than in all I have tried (to learn) and read the date.

Yours with best wishes, GEO. A. WOLFE.

Dear Sir:— Cincinnati, O., March 3, 1908.
Your book came to hand and I must say I am very much pleased with it. It is far the best book I have seen on poultry. The ideas set forth in the book, which are the results of your experimenting, certainly show that you are a little in advance of others in this work.

Common Era, Ill., March 19, 1908.
I have built several of the brooders as described by Mr. Philo, and at present time have young chicks, a week old, outdoors, healthy and strong, without being warmed by any artificial heat. Yours respectfully, WILSON BROOKS.

SPECIAL INTRODUCTION OFFER. We will send the book and right to use all patents and one year's subscription to Poultry Review for \$1.00.

POULTRY REVIEW, 23 Third Street, ELMIRA, NEW YORK.

CINCINNATI,

OHIO

Honey Markets.

The prices listed below are intended to represent, as nearly as possible, the average market prices at which honey and beeswax are selling at the time of the report in the city mentioned. Unless otherwise stated, this is the price at which sales are being made by commission merchants or by producers direct, to the retail merchant. When sales are made by commission merchants, the usual commission (from five to ten per cent) cartage, and freight will be deducted, and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage, and other charges, are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

EASTERN GRADING RULES FOR COMB HONEY.

FANCY.—All sections well filled, combs straight, firmly attached to all four sides, the combs unsolled by travel-stain or otherwise; all the cells sealed except an occasional one, the outside surface of the wood well scraped of propolis.

No. 1.—All sections well filled except the row of cells next to the wood; combs straight; one-eighth part of comb surface solled, or the entire surface slightly solled; the outside surface of the wood well scraped of propolis.

No. 1.—All sections well filled except the row of cells next to the wood; combs comparatively even; one-eighth part of comb surface solled, or the entire surface slightly solled.

No. 2.—Three-fourths of the total surface must be filled and sealed.

No. 3.—Must weigh at least half as much as a full-weight section.

In addition to this the honey is to be classified according to color, using the terms white, amber, and dark; that is, there will be "Fancy White," "No. 1 Dark," etc.

NEW COMB-HONEY GRADING-RULES ADOPTED BY THE COLORADO STATE BEE-KEEPERS' ASSOCIATION.

No. 1 WHITE.—Sections to be well filled and evenly capped except the outside row, next to the wood; honey white or slightly amber, comb and cappings white, and not projecting beyond the wood; wood to be well cleaned; cases of separated honey to average 21 pounds net per case of 24 sections, no section in this grade to weigh less than 13 1-2 ounces.

Cases of half-separated honey to average not less than 22 pounds net per case of 24 sections.

Cases of unseparated honey to average not less than 23 pounds net per case of 24 sections.

No. 1 LIGHT AMBER.—Sections to be well filled and evenly capped, except the outside row, next to the wood; honey white or light amber; comb and cappings from white to off color, but not dark; comb not projecting beyond the wood; wood to be well cleaned.

Cases of separated honey to average 21 pounds net per case of 24 sections; no section in this grade to weigh less than 13 1-2 ounces.

Cases of half-separated honey to average not less than 22 pounds net per case of 24 sections.

Cases of unseparated honey to average not less than 23 pounds net per case of 24 sections.

No. 2.—This includes all white honey, and amber honey not included in the above grades; sections to be fairly well filled and capped, no more than 25 uncapped cells, exclusive of outside row, permitted in this grade, wood to be well cleaned, no section in this grade to weigh less than 12 ounces.

Cases of separated honey to average not less than 19 lbs. net.

Cases of half-separated honey to average not less than 20 pounds net per case of 24 sections.

Cases of unseparated honey to average not less than 21 pounds net per case of 24 sections.

CINCINNATI.—The conditions of the honey market are not satisfactory, as there is no consumptive demand for either comb or extracted honey. Lower prices are no inducement. We must await the revival of business in general, which, no doubt, will be as soon as the weather settles. Quote our fancy water-white honey for table use at from 9 to 10, according to the quantity purchased. Amber extracted honey in barrels brings 5½ to 7, the price depending on the quality and quantity. There is an abundance of beeswax, for which we are paying 30 cts. in cash and 32 in trade for choice yellow, delivered here, free from dirt.

THE FRED W. MUTH CO.,

April 14. Cincinnati, O.

KANSAS CITY.—The crop of 1907 of both comb and extracted honey is pretty well sold out. What little comb is left shows signs of granulation. The demand is fair. We quote: No. 1 white comb, 24 sections, per case, \$3.00; No. 2 white and amber, ditto, \$2.75; white extracted, per lb., 7½. Beeswax, 25 to 27.

C. C. CLEMONS & CO.,
Kansas City, Mo.

April 20.

BOSTON.—White comb honey, fancy, 17; No. 1 white comb honey, 16; white extracted honey, 10; light amber, 9; amber, 8.

BLAKE-LEE CO.,
April 10. 134 State St., Boston, Mass.

ST. LOUIS.—The honey market has not undergone any change since ours of March 20. There is no demand for honey, and the quotations are nominal as follows: Fancy white comb honey, 15 to 16; No. 1, white and amber, 13 to 14; broken and defective, less; extracted white, in cans, nominal at 8½ to 9; amber, 7 to 8; in barrels, 6½ to 7. Granulated extracted honey sells at ½ to 1 ct. per lb. less. Beeswax is firm at 28½ for prime; impure and inferior, less.

R. HARTMANN PRODUCE CO.,
St. Louis, Mo.

April 11.

BUFFALO.—There is a fair demand for white-clover comb honey. Other grades are very much neglected. It is almost impossible to sell No. 2 white or mixed at even low prices. No. 1 fancy white-clover comb honey, 15 to 16; No. 2 ditto, 11 to 12; No. 1 dark, 10 to 11; No. 2 dark, 9 to 10. Beeswax, 28 to 30. Tumbler honey, 90 cts. to \$1.00 per dozen.

W. C. TOWNSEND,
Buffalo, N. Y.

April 11.

ST. PAUL.—Receipts are very light; demand moderate and prices steady. The prices below represent those obtained for shipment in small lots. Fancy white-clover comb, new, per lb., 18; fancy California, 24 combs per case, \$4.00; strained, in 60-lb. cans, per lb., 10.

W. H. PATTON, Sec. Board of Trade,
St. Paul, Minn.

April 22.

SCHENECTADY.—There is not enough doing in honey at present to be worth quoting. There is but little stock on hand, with an occasional order. The attention of the trade is now in the direction of maple syrup and sugar, of which there is a very good crop reported.

CHAS. MACCULLOCH,
Schenectady, N. Y.

April 20.

INDIANAPOLIS.—Jobbers are fairly well stocked, but very little honey is being offered by producers. Best grade of extracted honey is in good demand, but comb honey is finding slow sale. Jobbers are offering the following prices, delivered here: No. 1 and fancy comb, 15 to 17; extracted white clover, 8 to 9; amber, in barrels, 6 to 6½. Beeswax, 28 cts. cash or 30 in exchange for merchandise.

W. S. POWDER,
Indianapolis, Ind.

April 17.

ZANESVILLE.—The demand for honey continues quite light, and one or two of the smaller commission men are cutting prices. From No. 1 to fancy comb honey brings, when sold to the wholesale grocery trade, about 18 cts. Extracted is moving very slowly. The supply of beeswax exceeds the demand. I offer 30 cts. for best grade in exchange for bee-supplies.

EDMUND W. PEIRCE,
136 W. Main St., Zanesville, O.

April 18.

SAN FRANCISCO.—Prices on honey still rule as before, but every thing is closely held. There is a fair supply of comb, but extracted grades are almost cleaned up. It is said that the dry weather will cause a shortage, if not an entire failure of the crop, in some sections. We quote: Water-white, comb, 16 to 17; white, 15; water-white, extracted, 8 to 8½; light amber, extracted, 7 to 7½; dark amber and candied, 5¼ to 5¾.

Pacific Rural Press, April 18.

LIVERPOOL.—The honey market is steady and quiet, but stocks are not large. Fine quality meets with fair demand, but low grades are almost entirely neglected. We quote: Chilean, 4 to 6½; Peruvian, 3½ to 5½; California, 7½ to 9; Jamaica, 4 to 5½; Haiti, 6½ to 6¾. Beeswax is steady—African, 27 to 30; American, 30 to 33; West Indian, 27 to 32; Chilean, 30 to 36; Jamaica, 34 to 35.

TAYLOR & CO.,
7 Tithebarn St., Liverpool.

April 11.

CINCINNATI.—The market on comb honey is very quiet, there is hardly any demand. The price for extracted amber in barrels is 6c. We have no white clover to offer. California white sage is selling at 9 and 9½c.

C. H. W. WEBER,
Cincinnati, O.

April 23.

DENVER.—The market on comb honey is slow, and prices are declining. We quote to our trade, No. 1 white, per case of 24 sections, \$3.00; No. 1 light amber, \$2.85; No. 2, \$2.70; extracted, white, 8 to 9; light amber, strained, 6¾ to 7½. We pay 25 cts. for clean yellow beeswax delivered here.

THE COLORADO HONEY-PRODUCERS' ASS'N.,
April 22. F. RAUCHEFUSS, Mgr.

We're Modest Bee-supply People, but == We've Just GOT to Tell You about this Letter

It came from Mr. John M. Davis (yes, the Queen Bee Davis, known everywhere).

It was written to Mr. J. M. Buchanan, of the Tennessee Bee-keepers' Association, and—

We didn't know a thing about it until Mr. Buchanan wrote us: "I quote from a letter received from Mr. John M. Davis to-day (March 7, 1908):"

DAVIS DECLARES:

"I think the supplies you bought from Mr. Muth you will find about the best you have ever seen, judging from those I got from him some time ago. I have used supplies from nearly every manufacturer in the United States, and the makers of Muth supplies do the most perfect work of any I have seen."

Mr. Buchanan wrote us on March 2, 1908:

BUCHANAN SAYS:

"I must say this is the best lot of supplies it has been my lot to handle; they could not be surpassed."

With two **authorities** saying such things about **Muth's** Beeware, can **you** hesitate? There is never any gamble about them—they are **always** the best of their kind—everything a bee-keeper needs, and at factory prices here in Cincinnati. We charge no drayage to depot.

New Lands in The Northwest.

Montana, North Dakota, South Dakota.

Many who live in the Eastern States imagine the West has been fairly well settled by thrifty farmers—so much so that there is very little opportunity for a new comer to get in and do well. No greater fallacy could be entertained. The Northwest is just opening up, and infant empires are being nursed which are destined to cut a great path in the history of the world. This is no exaggeration, for Montana is nearly three times as large as England, and even richer in natural resources, besides being possessed of a splendid climate which enables the white man to work to his extreme capacity. There is an idea that the winters are bad, when it is actually true that they are more equable and pleasant than the winters of Ohio, Indiana, and Illinois. It is a fact that the thermometer goes down low in Eastern Montana and Western Dakota, but that is not for long; besides, the air is very dry, light, and invigorating. There are long spells of very pleasant weather in between the cold snaps. This makes the problem of wintering bees actually easier than it is in the Eastern and Central States. In summer there is no sweltering heat as in the States near the great lakes or the Gulf of Mexico. The summer days are long and pleasant, with cool

nights. If the farmer does a long days' work he always has the satisfaction of knowing the nights will be cool enough to allow of sound sleep under a cover of some kind. The crops of the temperate zone reach the highest state of perfection. Oats, barley, buckwheat, and clover are of the best quality, and, if well cultivated, yield much higher than in Illinois or Ohio. This makes poultry culture a success wherever tried with ability and persistence. It is practically the same with the bee industry. Clover, alfalfa, and many lovely wild flowers, render it a success. Of course, some localities are letter than others, and there are some places where it would be a failure; but this much is sure—bee-keeping in Montana and the western part of South Dakota and North Dakota, Idaho, and Eastern Washington and Oregon, is merely in its infancy. These States are extremely rich in mineral resources, so that mining is a prominent industry. These miners are well paid, and, as a result, there is a first-class local market for all honey produced. It is just the same with eggs, poultry, and butter, of course, or any other agricultural product of a similar nature. This being the case, there is seldom any necessity for the Montana farmer to ship long distances to find

a market for produce, unless it is wool, which is easily transported.

There is also an impression that the West is wild and woolly, and that children and delicately nurtured women have no place there. Just the reverse is true. In most of the States of the West, educational facilities are superior to those of the East, and good schools abound. By paying good salaries they draw as with a magnet the best teachers from the States further east. This process has been going on for years, and still continues. Churches abound. Every little town has its public library, and the latest ideas of the scientific and literary world are discussed as soon as presented. Under such conditions everybody is an optimist, believing all things are possible. The light, dry, invigorating air and genial sunshine have much to do with this. Consumptively inclined people gain a new lease of life, and the man with the "blues" is unknown.

Nobody wants for work; and the more people flock, the more work there is for all, and this condition of affairs will continue for many years—very probably a century or so.

Scattered over Western Dakota and Montana are fine tracts of land, either not settled at all, or sparsely so. Though rich and fertile, some of this land is still open to homestead entry. In many other localities of the Northwest the Chicago, Milwaukee & St. Paul Railway is building a new line which taps a new country all undeveloped.

In Fergus Co., Montana, for example, the area of land available for farming is over 3,000,000 acres, and at least 2,000,000 is fit for cultivated crops. This is rich land; and yet the whole country, having an area of 6762 square miles, has only a handful of people, and those who are there are largely interested in mining rather than agriculture, for it excels in the production of gold. It is safe to say 1,000,000 acres can be carved into fine farms if homesteaders will only come along and claim them. In the western and northwestern sections of Fergus Co. the land lies in the famous Judith Basin, which contains 2,000,000 acres or more of the finest kind of agricultural land. It was only in the summer of 1907 that one could reach this region by railroad, hence it is no wonder it has not been settled. It is the kind of land on which a good farmer may produce 40 bushels of wheat and 100 bushels of fat oats. Will it answer for bees? Yes; very soon the farmers will plant all kinds of clover, and the wild pastures will become white-clover meadows. Wild flowers are everywhere, and, what is very important, there are excellent markets not far away. Butte City, the greatest mining-camp in the world, with 80,000 inhabitants, is not so far away, and pays higher prices for produce than Chicago.

The capital of Fergus Co. is Lewistown, with 3000 inhabitants. Here is located the United States Land Office. It has all the leading churches,

and also a fine public hospital. It has all the "improvements" of a modern city, and quite, possibly in a quarter of a century may contain 100,000 inhabitants, as it has a splendid country all around.

Extensive coal-fields lie near by, and mineral deposits of all kinds are not far away. It will be very strange indeed if these American men do not create a great city there; and it will be a grand city with beautiful homes. There is every thing there to make it so. Nothing is now lacking but the right kind of people.

These States draw toward them the pick of the brain and brawn of the American nation. Somehow the other kind does not find its way to the Northwest, especially Montana. The sort of people now there are home-builders of the intensest sort. There is plenty of hustle, but women and children are splendidly protected, both by law and chivalry. Fergus Co. has been instanced as an example; but there are sections just as good—some of them not opened up yet to civilization, because railways are too remote.

The reason why we instance the Chicago, Milwaukee & St. Paul R. R. is because the line is absolutely new; in fact, several hundred miles of track will be constructed or finished this coming summer, and ere long it will reach the Pacific Coast. This gives the homeseeker a grand opportunity to get in on the ground floor. There is no need to go to Canada or Mexico when fine lands on a well-known railroad are so easily secured. If you are an American citizen you may lay claim to 160 acres of excellent land, or you may journey further westward and invest in irrigated fruit lands which will, in a few years, be worth \$1000 an acre if planted in apples, and the same properly cultivated. The railroad managers are anxious to get new people to settle near their property, for unless towns and cities spring up, their investment will prove a failure. They do every thing to facilitate the movement of settlers, and go to a great deal of trouble to furnish the desired information. Nothing would do more harm than for them to promulgate erroneous ideas of the country, and usually this work is delegated to men whose only interest in the work is the salary they draw. This prevents exaggeration and fanciful conceptions. While land is good and the conditions good, this is essentially a country for the hustler. It is no place for the man looking for something easy.

As a land of beauty it is unexcelled by any in the world. Not far away is the famous Yellowstone Park, where people flock from all parts of the world to view the scenery. And there is plenty of more scenery of the same kind all through the Northwest. It is the paradise of the sportsman and angler, and the elysium of the naturalist and geologist.

There are great forests for timber, and waterfalls for power. Taken all together it is a happy land.

FIX YOUR ROOFS.

Have you written for the little book on mending the old roof, published by The Anderson Mfg. Co., Elyria, Ohio? It's a good money-saving little book to read. Write for it. Just say: "Send me that free book on fixing roofs advertised in GLEANINGS IN BEE CULTURE."

TEMPERANCE POST CARDS.

Mr. A. T. Cook, of Hyde Park, N. Y., the well-known seedsman, is a prominent temperance worker as well. To help the good cause he has published a series of very nice post cards which cover temperance problems very well. Correspond with him if you are interested. See his ad't, page 597.

HARDY PERENNIAL FLOWERS.

It is pleasing to know that the hardy perennial flowers are becoming popular. They are so readily raised from seeds, so easily cared for, and withal so beautiful and lasting, that they are sometimes called "The Poor Man's Flowers," a name not inappropriate, as they do not have to be coddled and fussed over every year to have them grow and bloom.

Pansies and Daisies, which begin to bloom with the Snowdrop in early spring, soon usher in a wealth of snowy Arabis and Golden Alyssum and pink Carpet Saponaria. Then comes the Columbine in great variety, Campanula, or Bell Flowers, stately rows of Foxglove, and glowing clumps of Clove Pink, Sweet William, and Carnations, Forgetmenot, Feverfew, and a host of other beautiful and fragrant perennial flowers, making a rich array of color in the garden, and perfuming the air with delicious odors.

May and June are the months in which to sow these seeds to get the most satisfactory results, and if you get them and plant them at this season, you will never regret it. The plants are hardy, lasting, and free-blooming, and will afford a glorious return for the modicum of cost and labor of raising them. They will live and bloom well for years, and are a never-failing source of real garden enjoyment. Do not fail to start a bed of hardy perennials this season. See page 591.

SAVING

is more important than hard work.

Money deposited with us is secure and works for you continually. Our perfect system of Banking BY MAIL brings this opportunity to your door.

4%₀

The Savings Deposit Bank has a capital and surplus of \$70,000, and assets of over \$700,000. Its policy is conservative; its affairs are ably managed by capable and successful business men.

Deposits of \$1.00 and upwards accepted, on which we pay a yearly interest of 4 per cent, compounded semi-annually. Send currency in registered letter, your own check; or by P. O. or Express money-order.

**NATIONAL
BISCUIT COMPANY**

Purchasing Department,
Washington Blvd. & Morgan St.
CHICAGO, ILL.

HONEY WANTED.

Wanted to contract for 20,000 lbs. comb honey in shallow extracting-frames 5% inches deep.

Requirements: Honey to be produced on full sheets of extra-thin super foundation, in shallow extracting-frames, not wired.

Grade: Same as first three grades in GLEANINGS grading-rules—Fancy, A No. 1, and No. 1 (all included as one grade).

Quality: Honey must be produced from clover, bass-wood, or raspberry.

Combs must be even and of uniform thickness—not over one inch.

Will furnish frames, shipping-cases, and carriers for re-shipping the honey.

Bee-keepers in Michigan or Ohio interested in this proposition, write, stating approximate number of frames you can furnish, and price wanted for the honey per pound, *net weight*, F. O. B. Medina.

Address

HONEY BUYER,

c-o GLEANINGS IN BEE CULTURE,
Medina, Ohio.

WE WILL BUY AND SELL

HONEY

of the different grades and kinds.

If you have any to dispose of, or if you intend to buy, correspond with us.

We are always in the market for WAX at highest market prices.

LEAVING THE BUNCH BEHIND.

Along with marbles and baseball, renewed interest in wheeling manifests itself as a sure indication of spring and the joys of outdoor exercise.

Nothing ever invented serves so admirably the triple purposes of utility, exercise, and pleasure as does the bicycle. The best grade of wheels are now selling for less than one-third the prices of ten years ago, and at that the rider gets a better mount than was possible then. The coaster brake and two-speed-gear features alone mark a big step forward in bicycle construction since the boom days.

Inquiry among jobbers and dealers discloses a demand for bicycles, not only from the small boy (who has always ridden) but also from his older brother and his father also. The lady cyclist is also venturing timidly forth from the mysterious retreat wherein she has hibernated for a decade, and she's not in bloomers either—thank the Lord for that.

"Leaving the Bunch Behind" is the attractive picture adorning the gold-embossed 1908 catalog cover of the "oldest exclusive bicycle house in America," a copy of which has just reached us. The catalog is a work of art, and is brimful of valuable and interesting matter for riders or those thinking of buying wheels. It is well worth getting, and may be had by writing the Mead Cycle Co., Department SX-113, Chicago, Ill. They also send a wheel for ten days' free trial, and will engage live agents.

A NEW SPECIES OF CHICK-BROODER.

Almost anybody can use any of the standard makes of egg-incubators, and get fairly satisfactory results. It is when we come to take care of the young chicks that failure in many places takes place. The little things die from want of heat or too much of it, or they die from lack of fresh air; but, more than all else,

they die from from huddling too close together. In a word, they are "huddled" to death. A Mr. Root, of Cleveland, O., saw the need of a radical departure from the present-day brooder, and after considerable study of the problem he seems to have solved it. In his brooder are small hot-water pipes arranged in rows close enough together so that the chicks just manage to get their heads and necks comfortably through between them. This places a hot-water pipe on each side of the chick. The head of the chick is out in the fresh air very much the same as when underneath an old hen and the little heads pop out between the feathers of her wings. This gives conditions more in accordance with nature. The pipes are all hot alike, hence there is no huddling, and every wee thing has an equal chance.

Though on the market only a short time, the new brooder has met with flattering success, large orders having been obtained from Buenos Aires, Argentina, and even from places beyond the sea. The brooders are constructed by The A. I. Root Co., of Medina, Ohio, which is an excellent guarantee that they will be well made, because their bee-supplies are famous all over the world. Mr. Root, the inventor of the brooder, is no relative of the members of The A. I. Root Co. He is the organizer of The Root Incubator Co., Cleveland, O., where communications may be addressed.

SPLINTS VS. WIRES.

Perhaps you may have overlooked the article on splints in the April 1st issue of GLEANINGS by Dr. C. C. Miller who is the inventor. In that communication he reviews the whole question and a careful reading of it will be found useful by all bee-keepers who intend to use full sheets of brood foundation.

Bees For Sale.

My bees have wintered perfectly—clean, dry, and free from dysentery—and I have decided to sell a few colonies. The bees are of the Superior stock, the hives nearly new, in good condition, and well painted. The combs are all-worker—mostly built on wired foundation. Everything is strictly first class.

For a colony in an eight-frame Langstroth hive the price is \$6.00; in a ten-frame Langstroth, or in a new Heddon hive (two sections) the price is \$7.00; and to each purchaser of one or more colonies the Review will be sent free for 1908.

I am now ready to accept and book orders accompanied by the cash; and when I have received as many

orders as I care to fill, no more will be accepted. The bees will be shipped by express, about the close of fruit-bloom, when the newly gathered honey will furnish the necessary water, and safe arrival will be guaranteed in every respect.

If you wish to stock your apiary with a strain of bees that has no superior, here is a chance to get a breeding-queen, such as the most of dealers ask from \$3.00 to \$5.00 for, already introduced, in a full colony, whereby she can be shipped without injury, early in the season, all at a moderate price.

W. Z. HUTCHINSON, Flint, Mich.

BEE KEEPING

will be a profitable industry this season.

Honey is high—short crop last year. The shortage of the honey crop for 1907 in the United States warrants bee-keepers to increase their colonies. About a half crop was produced, and in California, where the cheap honey comes from, only a quarter of the average crop was produced.

Get Ready Now for More Honey

Let us send you our catalog. We are manufacturers and sell only our own make of bee-supplies. Minneapolis is the largest lumber-distributing point; the Mississippi river furnishes us power, and our organization and labor conditions are the best for economical production. Send us an estimate of your requirements and let us give you prices. We have a large stock of standard bee-supplies on hand. Dovetailed Hives, Sections, Section-holders, Separators, Brood-frames, Comb Foundation, Smokers, Extractors, Shipping-cases, etc.

## TO THE BEE - KEEPERS OF CANADA.

**W**E are pleased to say that we are able to offer, in Canada, goods manufactured by The A. I. Root Co. While we do not offer every thing listed in their catalog, we have selected such articles as we believe will best meet the wants of the Canadian bee-keepers.

The heavy duty and freight charges we have to pay make it impossible for us to sell in Canada at Root's prices. We have, however, made prices as low as possible, and in no case do we charge nearly as much extra as the amount of freight and duty we ourselves have to pay on the goods.

We would ask you, when comparing our prices with those of other dealers, to take into consideration the **QUALITY**. If you do so we feel satisfied that you will place your order with us. The splendid quality of the material sent out by The A. I. Root Co. has given "Root's Goods" a world-wide reputation. Remember, The best is cheapest."

Jamestown Exposition, 1907

IS THE BEST,  
STRONGEST,  
COOLEST,  
CLEANEST,  
CHEAPEST,  
AND LARGEST  
SMOKER SOLD  
FOR A DOLLAR

The perforated side grate seen above holds a removable, metal, asbestos-backed fire shell, preventing burning the tin off the outer case, and deflects the air at right angles, preventing back draft to the valveless bellows. The air, passing to the back and over the top, cools and expels the smoke, fanning the burning fuel at top or side till all consumed, giving cool smoke for hours from one filling. It can't clog. No top-heavy cap to choke with soot; no valve to fall; no holes shedding sparks or hot ashes.

Four years' sales prove its success beyond a doubt, expensive dies making it uniformly perfect as possible to devise. We confidently guarantee full satisfaction or refund the price.

Price, \$1.00; 3 for \$2.50; by mail, add 25c. each

Send address of yourself and Bee friends for 8-page leaflet on "Smoker," and facts about Bees and Queens, 80 pages, free.

## A Thrilling Rescue.

*By the Bee Crank.*

There was a young woman from  
Lynn  
Who was so exceedingly thin  
That, when she essayed  
To drink lemonade,  
She slipped through the straw  
and fell in.

Now, a bee that was loafing  
around  
Spied her rose-covered hat on the  
ground,  
And said, "Isn't it funny,  
What's become of the Honey?"  
Then, hearing her squeals,  
Dragged her out by the heels—  
If he hadn't, she'd surely have  
drowned.

They tell a good many  
bee stories and comb-honey  
yarns that test the credulity  
almost as much as this one,  
which, I admit on the face of  
it, seems improbable. I make  
the admission in order to draw  
the distinction clearly between  
fact and fiction. The following

statements are FACTS.  
I have the finest, clean-  
est, freshest, and larg-  
est stock of Root's  
goods that I have ever  
carried. They are ready  
to go on the same day  
your order is received.  
I sell them at Root's  
prices, and save you  
time and freight char-  
ges. Danz. hives,  
fresh new foundation,

section boxes, bee-smokers,  
veils, and a host of other need-  
fuls. My catalog tells all about  
them. Send for it; it's free.  
I pay 28 cts. cash for beeswax  
or 30 cts. in trade for goods.  
Send large shipments by freight  
and small ones by express.

## Walter S. Pouder,

# GLEANINGS IN BEE CULTURE

Published by The A. I. Root Company, Medina, Ohio

E. R. ROOT, EDITOR  
H. H. ROOT, ASST. ED.  
A. I. ROOT, EDITOR OF HOME DEPARTMENT

A. L. BOYDEN, ADVERTISING MGR.  
J. T. CALVERT, BUSINESS MGR.

Vol. XXXVI.

MAY 1, 1908.

No. 9

I SUPPOSED that feeding 20 pounds of sugar (made into syrup) was equivalent to adding 28 pounds of honey to the winter stores. According to Allan Latham, page 509, it is only 23 or 24. I accept the amendment.

G. M. DOOLITTLE, in that nucleus, where the queen with all drone comb laid worker eggs, p. 492, I wish you would tell us whether the workers first contracted the mouths of the cells. I have seen worker brood in drone-cells a number of times, but never yet unless there was a contraction of the cell-mouths.

"PROHIBITION in the South is having a remarkable effect upon the fruit consumption in that section, fruit growing in demand at almost the same ratio that liquor has vanished. An Alabama dealer in fruits claims that his books show double as much business in January and February, 1908, as in the same months in 1907."—*N. Y. Com. Bulletin*. Why will not the same rule hold with honey?

MY LENGTHY Scotch friend on p. 499, you have given us the best lecture I ever read on transferring; but why do you hurt my feeling by tying strings around your ankles? Bicycle trousers-guards, costing 3 cents a pair, are ever so much handier, and are they not just as effective? [You are right; but as our lengthy Scotch friend is progressive we know he will accept your correction. He probably did not have any bicycle pants-guards, and simply used a string in lieu of something better.—Ed.]

I HAVE traveled about considerably, visiting hundreds of bee-keepers in their homes, and one of the things that I have noticed is worth pages of theory, and it is this: *The*

*most prosperous bee-keepers are those who keep the most bees.*—*Review*, 93. Yes, Bro. Hutchinson; but were they prosperous because they kept the most bees, or did they keep the most bees because they were prosperous? A man prosperous with a few bees is likely to become more prosperous with more bees; but if he is not prosperous with a few bees will he be more prosperous with more bees?

S. D. CHAPMAN seems not in accord with the theory that bees from choice select too old larvæ for queen-rearing, and that the first batch of cells should be destroyed and the second used. For 25 years he has re-queened by taking away queens, allowing the bees to select their own larvæ, and there has been no deterioration. He also says, *Review*, 119: "Nature has so ordered that the best queens a colony can produce are those hatched from the *first cells started*; seemingly, they are better fed, more vigorous, and give better results." Sorry Bro. Hutchinson made no comment upon this.

J. E. HAND doesn't believe in the theory that brood-rearing will go on better with abundance of stores in sight than where the bees have only enough to use from day to day. He says, *Am. Bee-keeper*, 91: "I have never been able to see that the amount of stores in a hive above the present needs of the colony had any more bearing upon the amount of brood reared than the amount of wheat in my bins has upon the number of eggs my hens lay." Can we have any definite proof either way? [Perhaps not definite proof; but, in the language of the court, there is a great deal of "circumstantial evidence" that would seem to favor the contrary view.—Ed.]

SAMUEL SIMMINS says: "Queen-cells should not be removed if not near hatching—until after a queen has been safely inserted. By removing them in the first instance the bees are again thrown back to the original uncertain and restless condition; but all the time they possess queen-cells, especially if capped ones, they are in the natural condition of expecting another, and will almost invariably

accept a stranger, provided she be not old and worn." Is not this directly contrary to the general belief and practice? Which is right? [We do not know, but we suspect he may be right. It looks reasonable.—Ed.]

GOOD BRAINS must have been used in getting up those Colorado rules for grading, p. 400. With such rules, selling by the section is all right, wholesale and retail. No. 1 honey averages 14 oz. to the section, and the consumer can never get any thing less than 13½. One can omit separators, but he must pay for that privilege a tax of 1 lb. of honey on every 12 sections sold. [This will do more to discourage and stop the practice of trying to get along without separators in Colorado than any other one thing. The progressive bee-keepers of that State are to be commended for the action taken.—Ed.]

HOW LONG does it take to test a queen as to the storing qualities of her worker progeny? You can hardly introduce her (to say nothing of rearing her) early enough in the spring so that results shall be exactly the same as if she had been in the colony all winter. Say she begins her work in April; you can't really tell what she is till the close of the harvest the following year. Introduce her in the fall, or rear her in the hive *a la* Chapman, and you can say she is really tested not till she is a year old; and isn't that about as young as you can ever have a queen properly tested? [Yes, the only way to test for honey-gathering is to wait till the queen is a year old unless one lives where the honey-flow is late. The very best breeding queens, or those tested for honey, are always a year old at least. We believe that the rule is universal among the best breeders.—Ed.]

THE ADVANTAGE in change of name from "glucose" to "corn syrup" is only temporary. The name "glucose" is objectionable because the people have learned what glucose is. How long will it take them (more on the lookout than ever before) to learn what "corn syrup" really is, and then what good will the change of name do the glucose crowd? [You have not quite the correct point of view, and apparently we have been at fault in not making clear this matter of the glucose-versus-corn-syrup decision. Of course, it is unfortunate that the change of name should have been allowed. That in itself would be a tremendous advantage to the glucose crowd; but when a mixture of glucose and cane syrup was allowed to be called by a new name—a name *not* descriptive of the contents, and misleading as to its source—a powerful precedent was given for the misbranding of other foods. The intent of the national pure-food law is very plainly for labeling *every* thing just what it is. We bee-keepers, for example, are not allowed to mix tupelo and clover honey and call it "clover," although we may say it is pure honey. Neither are we allowed to make a mixture of sugar syrup and honey and call it honey; but, strangely enough, the glucose people may mix glucose with cane syrup and call it "corn syrup."—Ed.]

It will be noted that this issue is extra large, being the promised number that contains special instructions on early summer management for the production of honey.

#### PAPER-WINTER-CASE COLONIES NOT QUITE UP TO THOSE IN DOUBLE-WALLED HIVES.

THE former do not quite seem to have held their own with the double-wall chaff hives. Indeed, it is hardly to be expected that they would. Our paper cases have several folds of newspaper under them, but this would make a packing material only from ½ to 1 inch thick over the ¾ thickness of wood, or a total thickness of 1½ to 1¾. In double-wall chaff hives there is a clear packing-space of 2 inches filled with chaff between walls ¾ inch thick, or a total of 2½ inches. When this is contrasted with 1¾ it will be readily seen that the difference, so far as figures go, is very much in favor of the double-wall hive; but it must be said, on the other hand, that paper-packed colonies wintered almost as well, and far better than they would have wintered without any covering if the experience of former years is any criterion. It would appear that the remedy, to make one method winter as well as the other, would be to put enough packing under the paper caps so that the actual thickness of protection will be equal to that of double-wall hives.

#### SERIOUS CONSEQUENCES AS A RESULT OF SPRAYING FRUIT-TREES WHILE IN BLOOM.

MR. N. E. FRANCE, General Manager of the National Bee-keepers' Association, in his Information Bureau No. 8 says:

Mr. W. sprayed his orchard often during open bloom, and killed 55 colonies of bees on an adjoining farm. Mr. B., not far away, also sprayed his fruit-bloom, killing all his bees, leaving hives full of honey, which his two little boys ate of and died before doctor could be called (Oklahoma) See that your neighbors do not poison-spray open fruit-bloom. It is dangerous. Some State laws forbid it.

I have late reports from most of the States, and bees wintered well; honey prospects are also good. In 1907 the Western States had a fair honey crop; but owing to warm winter and bad financial conditions there are now several car lots left unsold. Many dealers are now well supplied with the 1907 crop.

I have had several complaints of bee-keepers shipping fancy comb honey in front of case with poor and uncapped sections in back. This lowers market, and I ask that you never be one of such.

We wish we had more particulars regarding the case mentioned, where all the bees were killed and two little boys who ate of the honey were poisoned to death. Perhaps Mr. France can tell us.

We are also glad to note that he is using his influence against the dishonest grading of honey. The influence of Mr. France and Mr. Rauehuss will mean much.

#### DR. WILEY ON GLUCOSE OR CORN SYRUP AS A FOOD PRODUCT.

WE notice through the current press that Dr. H. W. Wiley, of the Department of Agriculture, is credited with saying that glucose or corn syrup is not palatable, nor is it eaten as a syrup. He says that it has to be highly flavored with other syrups before consumers will take it. This is the statement:

I have spoken of maple syrup as an important food product. Other table syrups should also be carefully scrutinized in regard to their purity. We have in this country abundant supplies of syrup-making materials to provide for all the table syrups needed. The maple-grove, the sorghum-field, and the cane-field are ready to furnish all the table syrups that we need. There is no necessity any longer, if there ever has been, of using glucose as a basis of a table syrup. By itself it is not palatable, nor is it eaten as a syrup. When used it is very highly flavored with the lowest-grade products which are entitled to the name of either syrup or molasses. For instance, the final residue of a liquid character from the sugar-refinery is the most common substance used to flavor glucose when offered for consumption upon the table. Not only is it used for the flavoring, but its presence is usually designated by the statement that the syrup has a cane flavor. The table syrups of this country would be vastly improved if glucose were entirely eliminated from their composition, and if there were substituted for this mixed mass the pure products of the maple-grove, the sorghum-field, and the cane-field.

We do not think there are many consumers, who actually know the quality of pure glucose, or, under its new name, corn syrup, who will take issue with the statement.

#### IRRIGATED FARMS.

UNCLE SAM has quite a number of fine irrigation farms which he desires to sell on nominal terms to *bona-fide* settlers. These are located in Nevada, Montana, Wyoming, and other western States. In some cases the payment required is very small. Most of them are about 40 acres in extent. Particulars may be secured from the "Statistician," Reclamation Service, Department of Interior, Washington, D. C. Any of our readers who desire accurate details of any government reclamation project in the West can get particulars from the same source. Just now large projects are being opened, both by the United States government and the State government of Wyoming. The conditions are about the same as in Colorado, but the lands are probably a good deal cheaper, as Wyoming is a newer State.

W. K. M.

#### OUTLOOK FOR HONEY FROM SOUTHERN CALIFORNIA VERY POOR.

WE have just received a line from Mr. L. E. Mercer, of Ventura, one of the most extensive honey-producers in California, dated April 5, saying that the bee-keepers of California are up against one of the worst seasons they have had for years. He adds that there has been no rain since February; cold nights have chilled the brood to such an ex-

tent that many colonies are very weak, and some of them are in the condition of spring dwindling. He has let all of his help go, as he does not expect any honey-flow, and he is of the opinion that the same conditions exist over pretty much all of Southern California. Mr. M. H. Mendleson, of Piru, has written almost as discouraging a letter, except he thinks there is a chance for some honey yet.

While the prospects were very promising in the early part of the year, it now looks as if the California bee-keepers would have another bad year.

#### WHY WE OBJECT.

SOME may wonder why we bee-keepers object so strenuously to glucose as a food. There are several reasons, and it may be well to state them. First, in nine cases out of ten it has been used to fool the public; that is to say, consumers have bought it unknowingly or unwittingly. Second, it has been used to depress the prosperity of certain legitimate industries such as syrup-making, bee-keeping, and preserve-making. The man who tried to do an honest business could not compete with the competitor who used glucose, and sooner or later he had to acknowledge defeat.

After the passage of the new national pure-food law all this was, to a great extent, changed. But under the recent decision, by which it is permissible to call glucose "corn syrup," there is a big chance to fool the public again. Articles of food naming glucose as the main ingredient would not sell; but under the new name it may now masquerade as a newly discovered food product, and it will continue to go in the stomachs of consumers until their owners discover that they are paying a big price for the old-fashioned glucose with a flavoring to cover up its brassy twang.

Glucose was largely used in preserves such as jams and jellies. Many housekeepers will on no account buy store articles of this sort, and are compelled for this reason to put up their own preserves. Hundreds of thousands of women do this rather than buy in the store a concoction of stale fruit, glucose, and benzoate of soda. Possibly it would be nearer the truth to say that *millions* of women put up their own preserves.

In Europe, on the contrary, there is a vast industry in the manufacture of jams and jellies. This is more particularly true of England, where good jam may be purchased in any store. It is a great national industry, and much is exported. Formerly the United States exported a considerable quantity; but glucose and benzoate of soda killed that trade.

There is a third and even greater reason. The human palate revolts against glucose, and it has to be flavored before it is really passably fit to eat.

There is considerable resemblance between the case of glucose and oleomargarine. The latter threatened to destroy the dairy indus-

try of America, not because it was good, but because it was very frequently sold as butter. *Oleo destroyed our export trade in butter.* This trade went to Canada, which does not allow oleo to be made there.

Artificial vanilla destroyed the trade in real vanilla, though it is distinctly an inferior product to that made from the vanilla bean, and some say the artificial product is poisonous.

Artificial indigo destroyed the industry of growing indigo, once a southern industry of importance. The artificial dye fades, and the natural is everlasting; yet the substitute won the fight.

Our fine carpets and rugs are made by eastern nations who use no artificial dyes or shoddy. Our Navajo Indians make the best blankets with purely natural dyes. The result is, they get high prices from white men who prefer the real goods; and it is economy to buy the high-priced goods—they last for ever. It looks as if we were too smart in some things. In any event, it will pay the bee-keepers of America to watch the glucose industry.

W. K. M.

#### LIQUEFYING COMB HONEY, AGAIN; THE PLAN A SUCCESS.

FURTHER experiments in liquefying comb honey in an incubator, as related on pages 278 and 414, have been made, and we may state that the machine has been kept going on another lot of honey. We selected some comb honey that was candied solid, so that it was almost hard; but the cappings were intact. It took nearly a month to dissolve all the granules of the honey. At the end of that time the combs and cappings were intact, and the honey entirely liquefied. The honey itself was more waxy, of heavier body, and to this extent was actually improved. We are satisfied now that a comparatively small room, having a sufficient number of steam or hot-water pipes, could liquefy almost a carload of honey at a time. If the cappings were intact, such honey would be fully as good as if not better than when it was taken off the hives.

In the matter of regulation we can not conceive of any thing better now than having a ventilating-pipe connected with outdoors. This should be operated by a valve or door that will lift through the action of a thermostat, allowing the excess of hot air to escape the same as in an ordinary egg-hatching incubator. In addition, for safety, an electric thermostat set between the low and high point would notify the owner, by means of an electric bell, when the temperature was going above 105° F. And right here we may say that we found the best temperature for liquefying comb honey to be between 103 and 105° F.

It is well known that many a dealer will get a quantity of alfalfa honey on his hands, partly candied. Such honey usually sells at one-third or one-half price. If he can have a suitable hot room he can save this honey at a comparatively small cost. A very small hot-water boiler, with sufficient radiation if

hot water be used, would keep a room 10×10 feet and 8 feet high hot for a month, at an expense, we will say, not exceeding \$10.00 for fuel. If there be \$1500 worth of honey in the room it can be readily seen that the fuel item is practically insignificant.

#### OUR POLICY TOWARD UNPOPULAR OR UNORTHODOX TEACHINGS.

ONE of our old correspondents recently made the statement in one of his letters that he supposed that what we published without a footnote reflected our own sentiments, and therefore had our editorial indorsement as if we had written it. In reply we said that, while that may have been true at one time, it was now our policy to publish any fair and reasonable statement, even though such statement might be in opposition to the well-known views of the editors of GLEANINGS.

Where a correspondent is obviously wrong, and is clearly at variance with the best thought and modern practice, we feel it our duty to put in a footnote of caution to prevent the beginner from being led into expensive error. But where an unorthodox correspondent sets forth a proposition that has a semblance of truth in it, we feel that we should let it go unchallenged. To footnote every statement that seems to be beyond the pale of orthodoxy or our beliefs would make our journal simply a mouthpiece of the views of the editors, and we hope we are fair enough to believe that no editor is infallible. At all events, we do not claim to be. We desire to have GLEANINGS reflect all shades of opinion and practices, believing that a general discussion will in the end bring out the truth. At the end of that time we may or may not summarize the facts proven or brought out as we did in the plural-queen discussion.

Lately, when R. L. Taylor, of Michigan, stated that clipped queens were "an unmitigated nuisance," and that he preferred to restrain his queens with queen-traps instead, he was clearly running counter to the views of most bee-keepers in general. But as those views were clearly and fairly stated, we did not challenge them with a footnote, believing there was an even chance that he might be right. This called forth a rejoinder from Mr. Halter, and then from Dr. Miller in this issue. If we had made an effort to squelch Mr. Taylor at the start by a vigorous footnote, other correspondents would never have thought of writing to state their views, and there the matter would have ended. But who knows but this discussion, which is free for all, may draw out new facts to an extent that will cause a revision of opinion?

To exemplify this matter further, any one who would have been bold enough at one time to declare against spring feeding for stimulating brood-rearing, such person would have been branded a heretic; now, apparently, there is a sentiment against it. Suppose, for example, the editor of this journal had suppressed these communications advising

against spring feeding because they were counter to his notions. Suppose, again, he were to hold back all others of the same character—clearly he would be molding his journal to his own notion of orthodoxy, and in time GLEANINGS would be a one-horse publication.

These remarks on the policy of GLEANINGS are dictated by the one who has been longer at the editorial helm than any other person on the force—namely, E. R. R. We are heralding no new policy, but an old one that has been undergoing a slight revision.

U. S. DEPT. OF AGRICULTURE BULLETIN NO.  
110: CHEMICAL ANALYSIS AND COMPOSITION OF AMERICAN HONEY, BY  
C. A. BROWNE AND W. J.  
YOUNG.

MR. N. E. FRANCE, General Manager of the National Bee-keepers' Association, placed on exhibition before the convention that was held in St. Louis during the year of the exposition 100 samples of honey which he had obtained from members in various parts of the country. A larger and more representative collection of American honeys has probably never before been obtained. These, apparently, were subsequently placed on exhibition in the great exposition where they could be further seen and studied.

To Dr. E. F. Phillips, of the Bureau of Entomology, in charge of apiculture, belongs the credit of procuring these samples for the government. These were assigned to the Bureau of Chemistry, the head of which is Dr. Wiley, himself a sugar chemist, who in turn placed them with Dr. C. A. Browne, another accomplished and skillful sugar chemist, who subjected them to a long and searching investigation. Forty more samples were secured from elsewhere, notably from the Hawaiian Islands, where abnormal honeys are common. The pollen in the different samples was examined by Mr. W. J. Young, as a means of further identifying the source from which the nectar came.

Taken all together, we have as a result a brilliant contribution to the subject of American honey analysis, equal at least to that possessed by any other nation. Hereafter we have a guide to the subject that is safe, scientific, and authoritative, for Prof. Browne has so well done the work assigned to him that there is little left for others to do, though the author thinks he could have extended the investigation still further. It is to be hoped he will be allowed to do so.

With the data so carefully collected and tabulated, the pure-food authorities of this country are now in position to do justice to all the claims of the American bee-keepers. Some of the latter were just a little afraid the "big stick" might be applied to them, when, as a matter of fact, they were quite innocent of any wrong-doing. In this book the information is tabulated ready for use, such as a court of law requires in a pure-food case. Hitherto such information was unobtainable. In this way justice will be

promoted, and the interests of bee-keepers protected.

Some of the facts elicited by the investigation are quite new; for example, 20 per cent of the samples showed no signs of granulation. This is surprising. The two most important of the non-granulating honeys are tupelo and sage, both southern honeys of high purity and quality.

Evidently honey-dew is easily detected, for the report says, "The presence of much honey-dew in a sample could usually be detected by the very marked molasses-like odor and flavor." This looks simple enough, and yet it may be quite an accurate test.

It is almost unnecessary to say that an extended inquiry of this kind elicited a number of new facts; for example, on page 42 we find the following:

"The statement is sometimes made, that a pure honey will rarely polarize more than  $-20^{\circ}$  V. at  $20^{\circ}$  Cent., and that a higher reading than this, while not conclusive evidence of adulteration, may well be looked on with suspicion. This statement is hardly borne out by the analytical results given in the table, where 16 of the 100 honeys examined polarized more than  $-20^{\circ}$ , the results going as high as  $24.6^{\circ}$  in a tupelo honey and  $24.8^{\circ}$  in a mangrove." Tupelo honey had an invert polarization of  $-28.38^{\circ}$  at  $20^{\circ}$  C., and yet contained 7.24 per cent of non-sugars.

It is very evident from this that tupelo honey is of very high quality, and yet it must be admirably suited to the purposes of the baking trade. For a long time bakers have preferred southern honey for their uses, and it is evident they have a good reason for so doing. One result of the publication of this book will be to raise the selling price of tupelo honey. It is clear that it has been underestimated.

Errors in present-day methods of analysis were detected by the author. For example he says, "The error resulting from a neglect of the phenomenon of birotation in the calculation of sucrose in honeys by Clerget's formula has already been mentioned. Another very serious error is that due to the change in the specific rotation of the levulose of the honey after the inversion by hydrochloric acid. This error in sugar analysis has been so thoroughly studied by Lippman and others that no detailed study of it need be undertaken here. Folman, who has recently made an investigation of this error, shows by analysis that many honeys which, when analyzed by the Clerget method, appear to contain cane sugar, contain in reality none at all, the error in many cases exceeding 1 per cent." Adding his own experience, Dr. Browne arrives at the following decision:

"On account of numerous errors just cited in connection with the Clerget method, and the difficulty of introducing any correction for these errors, the determination of sucrose in honey, when accuracy is required, should be made only by the gravimetric method. A neglect of this precaution might cause injustice to the producers. Honey No. 23, for example, had been found to contain 8.95 per

cent sucrose by the Clerget method, a larger amount than that allowed by the standard (8 per cent)." This is an important decision for a government chemist to arrive at.

It may be well right here to state that the United States standard for honey is as follows: "Honey is lævo-rotatory, contains not more than 25 per cent of water, not more than 25 per cent of ash, and not more than 8 per cent of sucrose." Most sugars deflect a ray of light to the right when subjected to polarization in a polariscope, but honey deflects it to the left as much as 24 degrees, hence it is termed lævo-rotatory, or left-handed. This action is due to lævulose sugar in the honey. Honey also contains dextrose, but the lævulose seems to be the more powerful, and deflects the ray to the left.

The author made one very important discovery, one which is likely to be of far-reaching importance in the future determination of adulterations in honey. He says: "In other words, 50 per cent of the honeys examined gave a constant\* ranging from 26 to 28°; 80 per cent from 25 to 29°, and 95 per cent from 23 to 30°." He here refers to honeys which have been "inverted" by means of strong hydrochloric acid and then tested in the polariscope."

It is clear that a honey that does not come in between these figures is suspicious to say the least. This discovery is worth a good deal to the bee-keepers of America. He says: "*It will thus be seen that we have a constant for honey which will be as valuable in analytical work as the Reichart-Meissl number is in the examination of edible fats.*"

As regards moisture in honey, the average amount was 17.90, with a range of from 12.42 to 26.88. This shows that American honey is 3 per cent dryer than German honey, and German honey is dryer than British. This is due to our dryer climate; but honey-buyers ought to note this, and act accordingly. Nevada honey is dryer than that of Missouri, for the former had only 14.61 per cent of water, whereas the "show me" State had 19.57 per cent. It is a truism to say the locality having the highest rainfall has the highest percentage of water in the honey produced.

As we might expect, very careful consideration was given to the subject of honey adulteration in all its relations. From what we glean, it is abundantly clear that our greatest danger arises from adulteration by the use of syrup made from invert cane sugar. Glucose is easy of detection. The author thinks that, if bee-keepers were more careful in naming the source on the label, it would greatly facilitate the detection of adulteration, and that is undoubtedly so. He says bee-keepers are exceedingly careless, and apply the name of almost any flower, thinking that they keep within the requirements of the law so long as their product is pure honey. This is a mistake, and more care would assist the bee-keeper as well

as the pure-food officials. For example, if a sample of honey is labeled tupelo or sage, the official chemists could tell very quickly if it was by its behavior in the polariscope, as they know just what to look for at once.

A feature of the report is the examination of the honey-dew honeys of the Hawaiian Islands. There, almost the only pure honey comes from the mesquite, which was introduced there many years ago. In localities where it is common, mesquite yields largely of the very best quality of honey; but in the sugar-growing districts the bees feed on the exudations from the sugar-cane, caused by insects. This results in honey-dew honey, or right-handed honey. It will be remembered that Uncle Sam has refused to allow this honey to be sold as normal honey. If sold at all it must be denominated "honey-dew honey."

There is quite a list of methods given for discovering different kinds of adulteration. These will be extremely useful to food chemists everywhere, and it is in this the chief value of the work lies. Food chemists who are not particularly well versed in the latest modes of examining honey will find here just what they require, and no doubt this was the object of Prof. Brown's studies. We say this because some might think this is a book for bee-keepers, which it is not.

As a further means of detecting adulteration in honey, Mr. W. J. Young was detailed to examine the samples to discover the origin of the pollen in them. Almost all the samples contained several kinds of pollen. For example, catclaw honey from Texas contained, in addition to catclaw pollen, rosaceous, hop, mesquite, labiate, coniferous, evening-primrose, cruciferous cactus, magnolia, cotton, composite (three kinds), ellipsoidal (four kinds), and subtriangular types were also found. Goldenrod honey from Maine contained five kinds of pollen of the composite type, probably including dandelion, goldenrod, and aster. There was also white and red clover, cruciferous ellipsoidal (probably willow), basswood, rosaceous (raspberry), and ericaceous types. The subject of pollen is well illustrated. Possibly, in some cases, examination for pollen may be the quickest method of detecting fraud.

At the end is given an excellent bibliography of all the chemical literature of honey from 1892 to 1907. This is a valuable feature. These are mostly from German sources, but several are by Americans and Canadians. Not one is written by an Englishman. There are 89 monographs mentioned, so that the literature of honey is not small by any means. We note, also, that some French work of recent date is not mentioned in the list, probably because we go to Germany for our chemical knowledge. All together this is an excellent contribution to our knowledge of American honeys, highly creditable to all concerned. It may be purchased from the Superintendent of Documents, Washington, D. C., at the price of 30 cents. Five cents more to foreign countries. W. K. M.

\*Constant in this case refers to a certain range of reading allowable in honey on the scale of the polariscope.

## ABOUT HIVES.

"What kind of hive are you using, Mr. Doolittle?"

"A hive which holds the regular Langstroth frame. It would probably be called the Langstroth hive, but it is simply made of four plain boards, nailed together with square ends, just the same as an ordinary box would be made."

"But you used to 'bank' on the Gallup hive, did you not?"

"Yes. I used to think that the Langstroth idea, as embodied into a hive by Gallup, was all that could be desired."

"Did you ever try any other?"

"No. Have you tried others, Mr. Smith?"

"Yes. I have used the Weeks, Champion, Kretschmer's, Root's Simplicity, Quinby, Gallup, Langstroth, and American; and I came over to-day to ask you if you thought the so and so would not be better than any of those I have used."

"Whew! You almost take my breath away. Such a list as that! I should say that it was enough to satisfy any reasonable person that there is very little virtue in a *hive* as a means of securing a large yield of honey, to say nothing about adding another to the list."

"What do you mean? Does not the *hive* have a whole lot to do with the crop of honey we secure?"

"It may have much to do with the marketable shape in which we secure our honey; but so far as the amount obtained by a colony of bees is concerned, the *hive* plays no very important part. Gallup told us, nearly or quite forty years ago, that, if of sufficient capacity, bees would store as much honey in a nail-keg as anywhere, and no man has been able to contradict the statement successfully. Hives do not *make* honey, and there is no virtue in any *hive* as a honey-maker."

"Well, then, what about hives, any way?"

"Simply this; and this was just the thing I hoped you had learned by using so many different ones: That *hive* is the *best* whose brood-chamber conforms the nearest to the natural habits and wants of the bee, and also to the wants of the bee-keeper, so as to enable him to take what surplus honey the bees may store, in the *most marketable shape*. That is all there is of it."

"And you now think that the Langstroth will meet those requirements as well as any?"

"I certainly do, or I would not be using it altogether."

"Well, I am surprised. You may be right. But there is another thing I want to know about. What color is it best to use in paint-

ing hives? I painted one black, and this was the worst to cast swarms of any I ever had. Then I have had many that were painted red, but they seemed to get too hot in warm weather, and cause swarming."

"But don't you know that black or red hives will not draw too much heat if allowed to stand in the shade from 8 in the morning to 4:30 in the afternoon, as they should in all well-regulated apiaries, after they become nearly filled with bees and brood?"

"But mine stood in the sun."

"Then if your hives stood in the sun they should have been painted white, because that is the only kind of paint that will allow the hives to stand without great discomfort to the bees during hot weather. But you do not say how you found matters in the hives that were left unpainted. If your colonies were in unpainted hives, and your locality similar to mine, I think you would have noticed that colonies in unpainted hives did the best. If there is a single *good* reason that can be advanced for painting hives at all, except for looks, I have never seen it; and as I believe there is no such reason, and not being naturally proud, or greatly concerned about looks, I have for more than 32 years left all of my single-walled hives unpainted."

"Do you paint double-walled hives?"

"Yes. With double-walled hives the case is different, for then the bees are practically in an *unpainted* hive, even if the outer shell is painted."

"But we are told that it is economy to paint hives, are we not?"

"Most bee-keepers talk that way; but I believe this is a mistake; for if cost of paint, time of putting it on, etc., be taken into account, said cost will more than renew the hives as often as those unpainted become unfit for use. But I think the economy is the other way. If any man would give me \$1.00 a hive for the privilege of painting my single-walled hives he could not thus buy the privilege, for I should consider that I lost \$2.00 in honey, because in painted hives there is not so great an efficiency toward brood-rearing early in the season, and this efficiency applies mightily along the dollar-and-cent line, where the flowers which yield honey bloom early in the season, as does white clover."

"But you would paint the top or cover?"

"No. All hives need a shade-board to protect them from the fierce rays of the sun from 8 A.M. to 4 P.M.; and as this shade-board not only protects from the sun, but from the rain as well, the covers and hives need no further protection, as it is rare that the sun warps the boards or the water enters or stands on any part of the hive."

"My hives are under trees."

"But the bees want the sun, morning and evening, to do their best, and the trees do not allow this. With me, colonies under trees do not do nearly so well as those out in the sun, but having a shade just over the hive during the middle of the day. I have often wished they did, for in extreme hot

weather, shade is much more comfortable to work in than the sun. But the bees thrive much the best out in the sun, with a shade just over the hive during the hottest part of the day. My advice to you and all others is this: Try a part of the apiary each way, and then you will *know* which is best for *you*. Depend upon the knowledge you gain through experimenting for yourself. With this knowledge there will come a certainty which can not be had in any other way."

#### COMB HONEY IN CANADA.

There appears to be a regular stampede toward the production of comb honey during the coming season, probably on account of the high prices asked for and obtained last fall. Years ago comb honey sold in Canada at a figure as low as \$1.00 per dozen sections, and quite commonly for \$1.25 per dozen, with the result that many stopped producing it. I doubt the wisdom of an extensive move in the direction of an increased production. The prices of comb honey have not been maintained in Toronto. The dealers have plenty on hand, and Mr. Grainger and others have not been able to sell their stock, even at a reduction of 30 per cent on last fall's prices. During a visit, March 10, Mr. Grainger gave the names of several well-known bee-keepers who had been trying to dispose of comb honey. If the financial depression should continue, the prices on comb honey will suffer more than those of extracted; for at high prices comb honey comes more under the head of foods that can be dispensed with. These conditions have greatly curtailed the demand for comb honey. This is, in brief, the situation *in Canada*. Every one will, of course, use his own judgment in the matter.

#### WINTERING CONDITIONS OF BEES.

On p. 52 of the *British Bee Journal* D. M. M. Banff writes: "Bees have been much confined, and had few thoroughly good flights. Never, perhaps, have I seen more dead thrown out, and very seldom, if ever, have there been so distinct and general signs of the markings of dysentery. It may be owing to the past inclement summer causing an overplus of pollen-gathering—not only in the regular store-cells of this substance, but also in the honey in the capped stores, and the spotting is uncommonly dark and malodorous."

In Ontario, those who winter their bees outside depend more or less upon the bees getting a cleansing flight some time during

the winter. During the past winter, from early November till March 10 the bees had no proper flight, and a good deal of dysentery is again reported in localities where the honey-flow was not good last season, and where sugar-syrup stores were not supplied in sufficient quantities to carry the bees through the winter. I am more and more convinced that the only safe course to pursue, unless the bees are sure of frequent flight, is to feed sugar syrup for winter *if the honey season has not been good*.

#### COMB-HONEY PRODUCTION.

My article, "Bee-keeping in Quebec," should have read that the weakness in comb-honey production in that province is that the comb is not fastened to the sides and bottom, owing to the use of starters instead of full sheets. Thanks, Dr. Miller, for drawing attention to the matter. By the way, Dr. Miller and Allen Latham are having a profitable and friendly discussion on the question of bottom starters and other matters.

Mr. Latham, page 290, *GLEANINGS*, states, "Yet it is desirable to get the plump section, for the simple reason that it will sell better—sell better because the buyer thinks he is getting more honey for his money." That is true; but a much more important point is that a well-filled section is *very* much less likely to break in transit. Even at the expense of showing my ignorance, I will confess that, although I have noticed many differences in varieties and strains of bees as to comb-building, my attention had not been drawn to a difference as to the attachment of comb, p. 291; yet Mr. Latham may be quite right. It is certainly an exceedingly important point raised, and it should be followed up in *GLEANINGS*. I do not like those pesky German black bees any way, and am quite convinced that *every good trait* they possess can be found in other varieties.

#### BOTTOM STARTERS AND SPLIT SECTIONS.

Because I have written and spoken mostly on the production of extracted honey I am often credited with knowing nothing about the production of comb honey. Let me say that Mr. Eugene Secor judged my comb honey at the World's Fair, Chicago, and it scored the highest of any there. It was not taken with a bottom starter. I can, however, see that the *method* of putting the foundation in the sections may have much to do with the need or not of a bottom starter in the section. Again, Mr. Latham believes that it would be very objectionable to have the edge of the foundation show on the top and sides of the split section. Another one thinks the consumer will look upon this with suspicion. I believe I introduced the *split-top* section from England to this continent. It looks unsightly, but I doubt if it throws suspicion on the product. The consumer cuts the section out of the wood, and probably never sees the foundation in the split; and even if he does he ei-

ther knows what it is or does not know enough to know any thing about it. It is surprising how little people know about some things.

#### HOW TO REMOVE WAX CAKES FROM CANS.

Sometimes through rapid cooling the cake cracks, and the outside portion adheres tightly to the side of the can.

Mr. R. L. Taylor, at the last Michigan State convention, gave a good and simple method of loosening the cake in such a case. He advised turning the vessel upside down and pouring over it boiling water out of a tea-kettle spout. I find that this works well. The tin expands at once, being metal, and down drops the cake. Simple enough, but many have not learned it. [If the can is larger at the top than at the bottom, and if the sides are well brushed with thick soap-suds, the wax will almost never stick.—ED.]

#### APICULTURE IN OUR AGRICULTURAL COLLEGES.

And why not? Yet it is true that in only a very few has any special attention been given to this branch of agriculture. In Michigan, bee-keeping has been taught since the '60's. In several other States, especially in Colorado, good work has been done. That Michigan has set a good example appears from the fact that such men as Benton, Porter, and Hershiser are among her graduates. Bee-keeping is most worthy, and should no longer be neglected. It conserves the vast deposits of most wholesome nectar which otherwise must go utterly to waste; it gives a profitable and very delightful occupation to scores of our most worthy citizens; and, best of all, it insures cross-pollination of our plants, which is indispensable to the most successful agriculture, and without it, and that by our honey-bees, in many lines of fruit and vegetable growing, there would be no success at all. If all our agricultural colleges, which are doing such admirable work in other lines, would give to apiculture the attention that its importance demands, we should not only advance the industry by spreading information regarding bees and the production of honey, but we could capture men of rare ability who else will never be attracted to bees at all. There are many Clutes, Phillips, and Hershisers, could we only get them trended beeward, who would be bright and shining lights in the apicultural world.

I suppose that the first class in bee-keeping ever taught west of the Rocky Mountains was taught by me here at Pomona College,

in 1894—as fine and enthusiastic a group of young ladies and gentlemen as ever delighted a teacher.

#### BEEES SPREADING SCALE INSECTS.

Mr. R. F. Weir, Sunnyside, Washington, writes that at their "farmers' institute," at Sunnyside, much was said regarding the spreading of scale insects by the honey-bee. The special pest was the San José scale, and the fruit-men were loud in their complaints. There were very few bee-men present, and so the matter was very much one-sided.

This is another case where ignorance is loud with complaint, and where a little more knowledge would have made a very different showing. Like the case of the spread of pear-blight, there is some truth; but the conclusions are utterly misleading and wrong. It is true that all scale insects are spread while very young, and while they are crawling about on leaf and twig before settling down to their real business, which consists of sucking and growing. It is also true that most of this spreading is done by insects and birds. The bird or insect alights on the tree where the young scale insects are crawling about in search of the right place to locate, and these latter crawl upon the feet of the bird or roving insect; and as the latter fly to other trees, the young tiny scale pest is carried along. It is possibly true that, in rare cases, the bees may do some of this mischief; but surely it is very little that they do. The bees do not alight on leaf and twig, nor even on the fruit; and as the young lice are very rarely on the bloom, they are but little likely to be carried by bees. The little scale insects are so tiny that they walk about very slowly, and so would rarely crawl on the blossoms, and hence would almost never crawl on to the feet of bees. I have never seen the wee scale lice on flowers, though I am wont every year to examine flowers daily and most carefully with a good lens; and as seldom do I see bees on any part of the plant except the bloom, and so we may rest assured that bees are scarcely ever wrong-doers in this work of scattering the young scale. This accusation has even less foundation than that of the spread of pear-blight. There the bees do their part; but there are enough other insects so that the mischief would be as effectually done were there no bees at all. Here we may feel very sure that the bees do almost none of the evil.

We have before us Vol. I. No. 1 of *The Guide to Nature*, a magazine devoted to nature study, by Edward F. Bigelow. It is a beautifully gotten-up journal of 40 pages and cover; price \$1.50. It is well illustrated from original photos, and contains a range of subjects that will be of more than ordinary interest to nature students. It is seldom that the initial number of any magazine presents a nicer appearance than this, and we congratulate its editor. For particulars apply to Edward F. Bigelow, Stamford, Ct.

#### SPLIT SECTIONS.

Split sections have been brought before the public lately in a way that seems likely to induce some to adopt them, or at least to give them a trial. It should be remembered that the plan is by no means new. Fifteen years or more ago I knew of a man who used them to a considerable extent, and I believe the plan had been published some years before that. The fact that it has made so little progress since that time that most regard it as something new, while it does not prove the plan valueless, is, to a certain extent, indicative that it is not likely to be generally satisfactory. I believe the points of superiority claimed are, less time required to fill the section with foundation, and a better filled and finished section of honey. As to the first point, I think the difference would be so small that it would be hardly worth considering. On the second point I would be willing to concede a little superiority in results over ordinary methods, but one that is so slight, when better methods are followed, that I do not believe it begins to compensate for the objections to the plan.

Chief among these objections are the general appearance of the section and the color which it gives to the old belief in manufactured comb honey. It is beyond question that many persons unfamiliar with comb foundation would find in these sections with their margin of unaltered foundation proof positive to their minds of the artificial nature of the honey, and thus one of the most injurious things that ever happened to the honey market would be given new life and strength.

#### FOUNDATION SPLINTS.

I used a number of splints for supporting full sheets of foundation last summer, and found them very satisfactory for the purpose. I was never satisfied with the results of horizontal wiring except when used with heavy foundation and under the most favorable circumstances of temperature, etc. The old vertical wiring gave perfect combs, but it is hardly suited to the thick top-bars in such common use, and the wires on the tops of the frames are considerable of a nuisance when it comes to scraping burr-combs off from them. When I came to manufacture the first splints I used to experiment with, I very soon found that they were not easily made by ordinary methods. Such small articles were difficult to handle in circular-saw work. I soon hit upon a method, though, that made it very easy. It may be that the slicing method of which the editor has told

us is best suited to factory use, but perhaps there are some who, like myself, use a special size, or who want only a few to experiment with, or, for other reasons, want to manufacture their own, so I will give my method. I made them out of the ordinary sawed wood separators. Cutting single splints at a time was too slow; and cutting a number at a time was troublesome and inexact. Either way made rough work, and the saw had a way of scattering those light splints all over the shop. So I took half a dozen old separators, more or less daubed with propolis, put them in a press in a warm place for a few minutes, and then cut the lot up as though they were a single board. Eureka! Then I took new separators and piled them up, dipping each alternate separator into melted beeswax, then put the pile into a press until the wax was cold. This pile was then sawed up as though it were a solid board. The best work was done by a thin fine-toothed saw without set, running at a high rate of speed. With this I could readily slice off splints at the rate of 250 a minute, all nice and exact. The wax did not clog up the saw in the least; and as the splints were to be soaked in hot wax anyhow, it was no detriment, but an advantage in handling that they were stuck together.

#### FIXING UP OLD HIVE-CORNERS.

Perhaps bee-keepers in the East are not much troubled by hives gaping open at the corners; but in the dry climate of Colorado it is a very common fault, especially with the Dovetailed hive as it was made several years ago, with the top edge of the ends of the hives coming between the sides. The cracks thus made are very wasteful of the heat of the hive, and sometimes become large enough to admit robbers. This does not do much harm as long as they are occupied by strong colonies; but if you stack up such hives or supers containing honey where the bees can get at them, you are likely to have trouble.

To put such hives in order I have a pair of cabinetmakers' clamps, by the use of which the corners may be brought up square and true. While they are held thus they may be renailed, if nailing will hold them. If not, a strip of tin may be nailed around the corner, using small nails. This holds the parts together and closes up any crack that may be left. A coat of paint on such a hive after it has been fixed up will make it look about as well as ever, and good for years of service thereafter. Instead of the tin, a wooden cleat may be nailed across the end of the hive flush with the top. This makes the hive much stronger, but requires the use of a different cover from those in common use.

The Department of Agriculture's definition of honey, as given in circular No. 19, says that "Honey is the nectar and saccharine exudations of plants, gathered, modified, and stored in the comb by honey-bees (*Apis*

*melifica* and *A. dorsata*.\*" How much honey is there on the market stored by *Apis dorsata*? Why leave out the other races of bees?

## THE TRUTH ABOUT QUEEN-TRAPS.

How to Know the Conditions by Looking at the Trap; Managing Swarms Without Traps or Clipped Queens.

BY R. L. TAYLOR.

On p. 282 Mr. Halter makes reference to some suggestions of mine with regard to the use of the trap instead of clipped queens for the prevention of the escape of swarms. I am at a loss to determine whether he is animated by a desire to make a "drive" at me, even at the expense of the trap, or whether he is without much experience in the use of the trap for the purpose mentioned. If the former, I have no objection to make. I shall enjoy it as much as he so long as he avoids misleading insinuations concerning useful apiarian utensils.

He asks: "How can you manage a given number of yards with only one or two visits a week, simply relying on queen-traps? After an absence of five days you come to examine the apiary, is it not necessary to overhaul every trap and let out the drones? If you find a laying queen you are gratified; but if you find a virgin, was it a case of swarming or have you detained her from her wedding-trip?" And then on another visit, after heavy rainstorms and chilly weather he imagines he would find the traps full of dead drones and perhaps some dead queens.

For his relief let me say that it is not necessary to let out the drones unless he allows his bees to rear an abnormal number of them. Let them stay and die; or, if too many for that, drown them and teach the chickens to eat them. In either case it is a good riddance. Nor is it necessary to overhaul every trap for any purpose. It is only necessary to glance at each trap in passing. If the bees are simply hanging out they may lie in front of the trap, or even cover it; but they will not pack the trap itself. (It goes without saying, that hanging out *during* a honey-flow is the result either of ignorance or negligence; if *after* the flow, then swarms need

no longer be expected.) But if the trap is found packed with worker bees, that shows at once that a swarm has issued and that the queen is in the trap, and the colony can be dealt with as desired, without delay. If a trap is found with only a handful or two of worker bees there will be found there a virgin queen restrained from taking her wedding-trip. If a trap should be found containing a queen attended by no worker bees worth mentioning, it would be a virgin escaped from a rival, and is not wanted there. Thus the use of the trap is simple and effective, and swarming colonies quickly and easily managed.

Again, Mr. Halter fears the effect of heavy rainstorms and chilly weather, after which will be found, perhaps, traps with dead queens and some full of dead drones. But the drones are no deadlier than they would be if dead without the storm—more's the pity. Some of the bees may get wet in a case where a swarm has issued, but not so wet as in a case of simply lying out with no trap on the hive. It may be set down as certain that no bees will be injured by any rain or weather we are likely to have during the swarming season; and as for queens, they are every whit as safe from injury in the trap in such cases as they would be in the hive itself.

Not satisfied with condemning the trap, Mr. Halter attacks my plan of managing swarms with neither traps nor clipped queens, and says, "How disastrous, when several swarms with laying queens cluster together, and the victorious queen destroys the others!" Not at all. Such queens are not bent on destroying each other. Even if the swarms are only let alone they will often divide of their own accord. In more than one case where two swarms were hived together I have had one of them come out, leaving the other in the hive after they had been together more than a day. At all events, if the apiarist is "on to his job" it is very seldom that a queen is lost. Even a virgin, though she will be balled, is not often injured.

For catching swarms I use light poles so prepared that a basket may be readily hooked on to the upper end. When several unite, some of the bees are shaken into each of several baskets—as many as there are swarms or more. The baskets, as they receive bees, are hung on convenient branches when those having queens are soon distinguished from those without by the conduct of the bees themselves. Now, traps are adjusted to the hives prepared for swarms, and the bees poured out of the baskets before the traps, taking care to divide them equally. Then we watch for queens, driving the bees in with smoke. Whenever a queen is discovered she is slipped into a cage till all have been located; then those lacking queens are supplied at once from the cages. Very seldom need a queen be lost; and should one be, she need not be deplored at that season of the year.

I have never recommended the trap as equal to the personal attendance of an apiarist during swarming. It is not. But when

\* [We have been informed that Mr. Benton, then in the Department, appeared before the committee and requested that the race *A. dorsata* be added, as he was expecting to make a trip to the East, secure these bees, and introduce them in this country. Under present conditions there will probably be very little of their honey produced in this country.—Ed.]

such attendance can not be secured, then it is a very convenient and helpful substitute; and to prevent, as far as may be, an unjust prejudice against it in the minds of those for whom it may be a valuable servant, I have been constrained to attempt herein its vindication.

Lapeer, Mich.

## QUEEN-TRAPS VS. CLIPPED QUEENS.

What Proportion of Clipped Queens are Superseded? the Behavior of Swarms when Queens are Clipped.

BY DR. C. C. MILLER.

[On this same subject is the following article, taking the other side of the question. Of course, neither Dr. Miller nor Mr. Taylor had seen what the other had written in this issue. These two articles on the opposite sides of the question may call for some new rejoinders; if so, our space is open to both.—ED.]

On p. 19 of GLEANINGS I find the following, credited to R. L. Taylor:

"Clipped queens are an unmitigated nuisance at swarming-time. A swarm with a clipped queen behaves quite differently from one with an unclipped one, the difference being greatly against the clipped queen. These disagreeable features will disappear if the wings are left whole and a queen-trap is used; and swarms will mix much less with the trap. Moreover the trap furnishes perfect security against all absconding, which clipping does not do, for queens are likely to be superseded at any time for any cause without the knowledge of the apiarist; and when supersedure takes place a swarm will issue with the new queen, and away go bees, queen, and all."

Here I've been in the habit of looking through my colonies each year before swarming time, clipping all queens found with whole wings, and then feeling safe till the next spring, without its occurring to me that at any time a queen might be superseded and then a swarm go off with a new queen. I wonder, really, how many swarms I've lost in that way without knowing any thing about it.

But is not that matter of supersedure just a little overdrawn? "Queens are likely to be superseded at any time for any cause." Unless I am a very poor interpreter, that will be generally understood to mean that supersedure is just as likely to occur at one time as another. Is it not generally understood that supersedure takes place in the great majority of cases after the time of swarming is over? A great deal of opportunity for observation leads me to believe that the general understanding is correct.

Some time in April or May I go through my colonies and clip all queens found with whole wings. Throughout the season afterward I frequently see more or less queens in different colonies; and if supersedure "at any time" were so common as one is led to believe from what is said on page 19, I ought somewhat often to see a queen with whole

wings. On the contrary, it is a very rare occurrence. My assistant, who has had even more opportunity for observation than myself, and who is morbidly sensitive as to the matter of loss from swarming, says, "Very, very rare, indeed." I really think that matter of supersedure is very much overdrawn.

Still, there may be *some* supersedures after the usual clipping-time; and, if I rightly understand page 19, the new queen, after she gets to laying, is likely to go off with a swarm. Really, Mr. Editor, how much chance do you think there is for that? Gravenhorst, one of the best authorities on such matters, puts it down as an unvarying rule that a laying queen never swarms in the year of her birth if reared in her own hive. Indeed, some go further and say that no laying queen will swarm in her first year; but I am sure there are exceptions to that. But in the case of supersedure, the more guarded rule of Gravenhorst bars all danger. In an experience of more than 40 years with clipped queens, and with colonies never very small in number, if page 19 is reliable I ought to have had quite a number of losses in the way indicated. It seems to me they could hardly have been very many during so long a time without my having discovered some of them. I question whether I ever had a single loss in that way.

As to the naughty behavior of swarms that have clipped queens, I have had some experience in that line. I have had bees of more than one swarm unite, and I've had swarming bees return to the wrong hive. But I do not think I've had much serious loss in that way. If the bees of No. 37 should go into No. 45, No. 37 would gather less, but No. 45 would gather more. Yet I think there is some loss by it. But don't dream for a minute that swarms with clipped queens have a monopoly of that sort of business. Swarms troubled that way before ever queens were clipped, and I've heard and read of more swarms uniting with unclipped queens than I ever had unite with clipped queens. A reputable text-book before me tells of how "as many as a dozen have been known to come out in this way, and go off to the woods in a great army of bees." I think I had never more than four with clipped queens to unite at a time. And I had no trouble fishing queens out of the united cluster as I would have had with unclipped queens. Nor did they ever go off to the woods.

Concluding, the beginner is practically told, "Don't clip, but put a queen-trap on each hive, and then you'll be all right, for every queen, laying or virgin, will be caught."

Don't you think that the natural thing will be for at least some of your readers next spring to put queen-traps on all colonies and then feel the thing is settled for the year? Certainly I've known more than one to think that would work, and without having read p. 19 at that. Then when it comes time for a colony to swarm, the swarm will issue and return, perhaps repeating the performance for several days, then the queen will be killed, a virgin will be prevented from taking

her wedding flight, and so become a drone-layer, and the destruction of the colony will be just as certain, although not so speedy, as if it had been brimstoned. How is one to know that swarms with clipped queens are so much more naughty in their conduct than swarms with queen-traps? Has some one learned it by actually trying the two side by side? I never had much experience with queen-traps, but I've had quite a bit with caged queens, and the trouble with their swarms was greater than with clipped queens allowed to hop out of the hives. Possibly it was reasoned out. Well, tell us the reason why a swarm should act any worse with its queen hopping about than with its queen in a trap. When the swarm issues, do you really think the bees know whether their queen is on the ground or in a trap? Certainly they can't know any thing about it without going back to the hive; and in any case where a swarm went back to its own hive I never knew it to trouble further by going to other hives or uniting with other swarms.

How much ventilation, Mr. Editor, is shut off when a queen-trap is applied? I suspect that at least one-half is always shut off, and in some cases four-fifths. Don't you believe that loss of ventilation is a very serious objection to traps? On the whole, would you advise a beginner that it is better to trust to traps than to clipping?

P. S.—A certain inquisitive person not far from my elbow says: "Do you think Ernest keeps traps on his hives? I wish you'd ask him how many traps he keeps on them."

Marengo, Ill.

[Dr. Miller asks us how much ventilation is shut off when the queen-trap is applied. We do not know; but not much, we suspect. As we figure, the perforated metal or bars in the trap have four times the area of passage of the average  $\frac{1}{2}$  in. deep entrance, or twice the area of  $\frac{3}{4}$  deep. The wire excluder would form less of an obstruction to ventilation than the perforated metal—how much we do not believe any one can positively determine.

In answer to his last question, we would say that a good deal depends on conditions. If we were running for the production of honey—well, we will state our position after our correspondents close the discussion. Our own opinion at this time would be premature. Some, accepting the opinion of the editor as final, might not give much weight to the opinion of one or the other of the correspondents.

In answer to the postscript we may say that we have traps on many of our hives in all of our yards, not to catch swarms, but to restrain and kill impure or undesirable drones. As a matter of fact, in a queen-breeding apiary one ought to use a great many traps, leaving only drones from extra select queens to have the freedom of flight. In this way we are enabled to bring about a selection of drones, and, to a large extent, the control of the male parentage of our bees for business.—Ed.]

## HOT-WATER SYSTEMS OF WAX-RENDERING.

### Some Comments and Suggestions.

BY OREL L. HERSHISER.

I have noticed Mr. Holtermann's comments on wax-presses, page 210. Having examined the wax-extracting proposition in many repeated experiments, with a view of determining the efficiency of the various methods employed in the production of wax, I respectfully desire to file an exception to Mr. Holtermann's statement that, "in a hot climate, or where wax-rendering can conveniently be left until hot weather, the method of heating the wax in a vessel on the stove and then pressing in a machine not on the stove, is perhaps the cheapest machine and the most rapid and economic method." Mr. Holtermann's "perhaps" may imply a slight doubt in his mind as to whether his statement would exactly fit the facts. True enough, the method will "answer well;" there are many inferior methods. I have profound respect for the opinions of my friend, believing them to be the expression of conscientious convictions; but sometimes conclusions are reached without sufficient data upon which to base them. Many and repeated experiments enable me to make the counter-statement that, all things considered, there is a cheaper, more economic, and convenient method, not only for winter but also for summer wax-extracting.

Referring to the Hershisier wax-press, Mr. Holtermann states that "it takes considerable time to heat the machine and its contents." If it takes a given time to heat a wax-press and its contents of cheeses of comb or slumgum submerged in water, it is obvious

Hershisier wax-press.

that, for the same capacity of tank, or volume for volume, it would take the same time to heat the material in a separate boiler where the slumgum must be dipped over into the press-tank, cheeses formed, and the same submerged in water. This fact is so clear that "he who runs may read." Besides the necessity of performing the operation of dipping the slumgum from the boiler into the press, enough hot water to submerge the cheeses must be dipped into the press-tank, which necessitates the raising to the boiling-point a like amount of cold water to replenish the boiler for melting the next batch of comb. Hence, if there is any advantage in the time required to heat either of such presses and their contents, volume for volume, it lies with the press-and-boiler-combined machine.

My press is designed primarily to be used over the fire; but if one really prefers to melt

the comb in one vessel and then dip it over and press in another, such preference surely would not bias him against it, as there is absolutely nothing in its construction that would in anywise hinder him from doing so. In fact, it is as well adapted for use in that way as any press could be. Further, the directions for operating it explicitly state that, "when rendering comb that contains a large percentage of wax, or in converting cappings into wax by the hot-water process, it is advisable to melt the comb or cappings in another boiler and dip out all the wax that can readily be secured," etc. This direction, while strongly suggesting the adaptability of the press for use when not over the fire, does not contemplate the pressing of the cheeses in any other way than in boiling water over the fire. This exception to the directions is made to meet the requirements where the material to be pressed is exceptionally rich in wax, and to enable the making of the cheeses of such thickness as can be most economically pressed. This manner of handling cappings or rich comb avoids unnecessary operations of the press. The hot water may be used as often as is desirable by drawing it off into another vessel to be saved while the extracted cheeses are being removed, and others, that have been made ready while the extracting of the first lot was in progress, replaced in the extractor, when the hot water may be returned. During the short time necessary to empty and refill the extractor the water will lose but little heat.

By keeping the water surrounding the cheeses at the boiling-point while pressing, we facilitate the escape of wax from between them as a result of the motion of the water. By releasing the pressure, after it has been on a short time, there is a marked agitation of the water as though it were boiling violently, which is undoubtedly due to the escape of steam from the interior of the cheeses, generated there in considerable quantity, and confined by reason of the pressure, but which bursts forth when unrestrained. This escaping steam operates to open up the cheeses, and, when thus expanded, they absorb hot water to the limit of their capacity. When pressure is resumed, violent agitation of the water again occurs, which is, perhaps, due to forcing the steam from the interior of the cheeses where it has generated and been held from free escape by them, at a more rapid rate than it would escape without pressure. The hot water, being forced from the cheeses by the pressure and steam, conveys the wax with it, and a few repetitions of pressure, under these conditions, will leave the cheeses almost free from wax. Thus the extracting is more thoroughly and rapidly accomplished than is possible where the pressing is done without the aid of boiling water.

Such injury to wax as obtains from overheating will result whether the comb is boiled in a separate boiler or in the extractor. If the quality of the wax is injured by long-continued heat and boiling, it is necessarily due to the inattention of the operator, no matter what process of cooking and pressing

is employed. A hot-water wax-press, possessing easy facilities for drawing off the wax as fast as it accumulates on the surface of the water, enables the careful operator to commence drawing off immediately after the first pressing, and as often thereafter as there is an accumulation worth while.

Theoretically, bringing the temperature of the melted comb slightly above the melting-point of wax is all that is required in extracting; but in practice it is best to bring the material to the boiling-point, as an abundance of heat is preferable. We might have too little heat if we tried to have just enough. Short-time boiling has not been found to be appreciably injurious to wax. My experience has been that wax made by the boiling-water process is not discriminated against by the most extensive comb-foundation makers and other large consumers.

We are able to secure considerable of the last tailings of wax by the hot-water process, not otherwise profitably obtainable. Admit, for the sake of argument, that these last remnants are not obtainable without slightly injuring their quality. If we secure such wax we have something of good value we should not otherwise have had, which we should be as foolish to spurn as we should be if we rejected the lower grades of honey. But the quality need not be injured. At all events, let us have more wisdom than Reynard, and not regard these last remnants as "sour grapes."

Buffalo, N. Y.

## WAX-RENDERING.

Further Comments on the Sibbald Wax-press as Discussed by Mr. Holtermann.

BY C. A. HATCH.

I have been looking over GLEANINGS for Feb. 15, and, of course, saw the Sibbald wax-press article by R. F. Holtermann. If you will look up the matter you will find the same thing in principle described in "Langstroth on the Honey-bee," under the head of "The Cary Wax-press," if my memory serves me right.\*

The first press I ever made was identical except the racks, which Mr. Sibbald has covered on both sides with screen wire cloth. This I infer from the picture, as nothing is said about it in the article. In my press the racks were used with no covering. I used it by setting it directly on the stove. Mr. Sibbald uses another vessel in which to boil the wax, which I can see would be quite an improvement. He pours water over the press when ready to squeeze—something I never did. He also covers up the press while hot. This, also, I never did. I discarded the arrangement as I used it, on account of the mess in getting the pressed slumgum out of the press ready for a new batch. If there

\* We do not find any such reference in Langstroth, either in the new or old editions. We do find a description of the Cary press in the A B C of Bee Culture, old edition.—ED.

was only one batch or filling for the press to be melted, it worked quite well; but to make a 100-lb. lot with it was too slow and messy. His way of working it may have overcome these faults.

I have used the new Root-Hatch press twice, and have just two faults to find with it: It is too small; so, also, is the screw, which is too small, for it springs sidewise too easily. I think there is a chance for improvement over any of our present wax-rendering methods.

Holtermann's caution about wax needing constant watching for fear of boiling over and setting fire to the building is good. I set my house on fire once that way; and if there had not been help right there serious damage would have been done.

Another thing should be mentioned. Mr. Holtermann says, cover the form with cheese-cloth, fold over, and pin. Cheese-cloth as known in the United States will not do at all for such purpose. It is a thin loosely woven cloth of cotton. What Mr. H. means is a stout cloth made of linen, such as our cheese-makers use to cover their vats and curd with before pressing.

Richland Center, Wis.

### UNCAPPING-BOXES.

**Melting the Cappings as Fast as They are Sliced from the Combs; Another Machine for Rapidly Separating the Honey and Wax.**

BY J. Y. PETERSON.

The engraving shows my honey and wax extractor for handling cappings; and, as you will see, a capping-table, etc., all complete, for which I have recently applied for a patent.

The cappings and the honey drop through the hole in the top of the table, and fall di-

rectly on the tank filled with boiling water, and the mass at once melts and drains off into the receiver, where the honey goes to the bottom and the wax to the top. When the division line reaches a certain level the hon-

ey escapes to the main honey-tank into which the honey runs; also from the honey-extractor. I used one of these machines for extracting several weeks, and it worked perfectly, and at the end of each day I had no cappings, etc., to use up time. On the following morning I always had a perfect cake of wax ready for market after removing it from the tank. It was then necessary only to light the burners and go ahead. Any water that might get into the wax and honey from the uncapping-knife goes out in steam immediately, when it gets on the tank and the honey and wax slowly drain down the one-inch incline. It takes but a very small flame to keep this tank hot. The uncapping-knife is heated in the well for the purpose, which is a part of this tank; any steam that may generate escapes through this, and you always have a hot uncapping-knife, and can here also see when the water is getting low, and pour more in.

Besides the one I used I made three others for friends, and they used them with equally good results. I used No. 30 galvanized iron for the tank, which is 3 ft. long, 1 inch deep, and perfectly flat, with a rail on sides and back as shown.

The honey from this machine is not in the least colored, as is the case in the old sun extractor, and the wax does not need remelting, etc. You are through, and have a finished job each day. The honey has also a good heavy body. Because of the evaporating process it goes through draining over the tank. Not one particle of wax escapes with the honey, as the honey drains from the extreme bottom of the receiver.

While the sketch is not exact, you can get the idea. The burners should be close to the bottom of the tank. One five-gallon can of gasoline lasted me one season.

San Francisco, Cal.

[There is no question in our mind but that an uncapper embodying the principle

The cappings, as fast as they are sliced from the combs, fall into the hot pan, where the wax is melted. The wax and honey run to the end of the pan, and thence into the separator at the end.

rectly on the tank filled with boiling water, and the mass at once melts and drains off into the receiver, where the honey goes to the bottom and the wax to the top. When the division line reaches a certain level the hon-

(namely, melting the cappings as fast as they are shaved off the combs) is as correct in practice as it is in theory. Those who have tested it pronounce it a success. They further claim that the honey that goes with

the cappings is not affected as to its quality, because it quickly passes over the heated surface that melts the wax and both run into a receptacle where they cool. It is well known that a *quick* heating of honey, even though the temperature be raised above the melting-point of wax, 145 degrees, to prevent granulation for bottling purposes, does not appreciably affect the flavor of the honey, and apparently it would not with a machine of this kind. If any one knows to the contrary, let us hear from him. We know that, in a solar wax-extractor, the honey and wax run together. Because of the slow melting, the flavor of the former is impaired.

The fact that, after a day's uncapping, the honey and the wax will both be in marketable shape, is a strong argument in favor of the new method. The old uncapping-cans or boxes necessarily have to have a large enough capacity to take a day's cappings or more. After a day's work they must be allowed to stand until the cappings drain dry, after which they must be separately handled in a wax-extractor.

Mr. L. E. Mercer's outfit, which we illustrated on page 218 in our issue for Feb. 15, is of very simple design, having the advantage that it allows for the storage of a lot of combs just prior to their being put through the extractor. In this one respect it is superior to the one here illustrated by Mr. Peterson; and it is also superior in that it is simpler in design, and its construction will cost less.

An American patent has just been granted, under date of Jan. 8, to F. R. Beuhne, of Victoria, Australia. On examining the claims it would appear to us that the basic feature of melting the cappings as fast as they are shaved off the combs, by any and all means, has not been covered; but apparently the receptacle for heating the uncapping-knife as shown in the illustration of the Peterson machine is covered; so also a combination of horizontal tubes that are designed to receive and melt the cappings. But such tubes, in our judgment, are not material to the broad principle of melting cappings in some other manner.

Two other men, one in California and the other in Texas, claim to have used the principle for over two years. Just what effect this will have on the Beuhne patent we are unable to say. The situation seems to be somewhat mixed up; and for the present, at least, some time will have to elapse, perhaps, before it is fully determined who owns and controls, if any one does, the broad principle of melting the cappings as fast as they are removed from the combs in some manner *other* than that shown in the Beuhne patent.

We see no reason, however, why any one could not make a machine at the present time on the lines described on page 218, Feb. 15. But any one who makes such a machine would have to hold himself in readiness to pay royalty, possibly, to some one who could establish his rights to priority in the invention.—ED.]

## TRANSFERRING TO SECTIONAL BROOD-CHAMBER HIVES.

How to Prevent Swarming, and at the Same Time Force the Bees to Work in the Supers from the Beginning of the Honey-flow.

BY J. E. HAND

"I should like to try a few sectional hives the coming season. How and when can I transfer my bees to these hives with the least loss to the colonies so treated? My bees are in ten-frame Langstroth hives, and I want to produce comb honey."

Mr. Editor, this is a fair sample of many letters that I have received during the past season, and with your permission I will answer them through GLEANINGS.

### WHEN TO TRANSFER.

Assuming that your bees are in good condition, and that the hives are well stocked with bees and brood, and that each colony has a good prolific queen, the best time to transfer is at the beginning of the honey-flow from which you expect to get your surplus honey crop; hence it is very necessary that you thoroughly understand your location and the exact time of the blooming of the flowers of every honey-producing plant in your vicinity, and especially those from which your main flow comes, so as to have your dish right side up to catch the honey when it comes.

### HOW TO TRANSFER.

Our new hives should be in readiness, consisting of two shallow brood-chambers with frames of foundation, and a super filled with sections and foundation. The super should be separated from the brood-apartment by a queen-excluding honey-board. We will now begin work by removing the hive that we wish to transfer from its present stand and place it back and a little to one side (entrance in the same direction), so as to be out of range of the flying bees, and at the same time be handy to operate. In doing this we place the new hive on the stand from which we took the old one. After blowing a little smoke into the entrance of the hive, and rapping on it a few times so as to cause the bees to fill their honey-sacs, we will open it and find the queen, and shake her off the comb in front of the new hive, together with the bees that are on the comb with her, letting them run in at the entrance, being sure that the queen is in the new hive.

We will proceed to shake the bees from the remaining combs in like manner, leaving enough bees on the combs and in the hive to care for the brood. We now have our bees and queen in a new hive with full sheets of foundation in both frames and sections. Those the bees will immediately begin to draw out into combs, since the honey-flow is already begun. When the bees in the new hive have commenced work nicely on the foundation, say in 48 hours after transferring, we will remove the bottom brood chamber,

shaking the bees out in front of the new hive. We now have our colony in one shallow brood-section, with a section-super above, and separated from it by a queen-excluder. This is allowed for a few days only, or until the bees get well at work in the sections, when it will be removed.

In this way we force the bees to begin work in the sections at once, and at the very beginning of the honey-flow, and not only get *all* the honey in the sections, but at the same time do away with all swarming. We gave the two brood-sections at first to keep the bees from swarming out, which they are quite apt to do if hived directly into a contracted brood-chamber.

Having our bees nicely at work in the sections we will give them the brood-section that we took away, placing it at the bottom as before, and the work in the sections will not be in the least slackened by adding this room at the bottom of the brood-chamber.

In two or three days after transferring we will place the old hive close up beside the new one, with its entrance in the same direction, where we will leave it for a week or more, when it may be removed to a new stand and allowed to build up for winter to be treated in the same way another season.

Or if the hives and combs are old it is allowed to remain beside the new hive for 21 days, or until the brood has all hatched out, when the bees may be shaken down in front of the new hive, and the now empty combs be rendered into wax. In either case the bees returning upon removing the old hive will reinforce the new colony, thus keeping it in excellent condition for work in the supers.

This is known as the Heddon system of modern transferring, and was given to the bee keeping public some 25 years ago. It is also used and recommended as a means of swarm control when working for comb honey, and for a fairly good location with a sharp honey-flow it will give excellent results.

No matter what kind of hive your bees are in, you can in this way force them to begin work in the sections at the very beginning of the honey-flow. However, it is not a complete success unless used in connection with the sectional hive, for which the system was originally intended.

Expansion and contraction are important factors in successful comb-honey production—expansion up to the time of the main honey-flow, so as to get a strong force of workers, and then contraction in a new hive, so as to force the bees to enter the sections at the very beginning of the honey-flow, and at the same time do away with swarming. In this way box hives and odd-sized hives may be worked year after year, each season driving the bees into contracted hives as above described, thus securing a fine crop of comb honey. We do not advise the destroying of good hives and combs simply because they are of an odd size, for these hives are often good wintering and breeding hives.

Birmingham, Ohio.

## BOTTOM STARTERS IN SECTIONS.

**The Advantage of Full Sheets of Foundation: Producing Both Comb and Extracted Honey in the Same Super.**

BY F. W. HALL.

I never put a section on a colony unless it contains a full sheet and also a bottom starter of extra-thin super foundation. Anything less than a full sheet proves to be false economy.

Full sheets are not as good without the bottom starter; and the quickest way to be convinced is to try sections with and without, side by side in the same super—not only one super full, but hundreds of them; and long before the first twelve supers are taken off no magnifying-glass will be needed to tell the difference.

Full sheets of extra-thin foundation will stretch or sag with the warmth and weight of the bees from  $\frac{1}{16}$  to  $\frac{1}{8}$  inch or more, which brings the bottom and top starter almost if not quite together, resulting practically in a straight full sheet in the section. If simply one full sheet is used, too many will not be attached to the bottom of the section all the way across in a light colony or during a light honey-flow. On the other hand, if the foundation reaches to the bottom at first, the sag causes it to buckle, and the wrinkle at the bottom is far too often finished in an unsightly manner, and sometimes not finished at all. On the concave side the cells keep running closer together, and an occasional cell will be left out, and still it will not be greatly noticed; but on the convex side, the cells get wider and wider until the limit of capillary attraction is reached for holding the honey in the cells, and the bees are then obliged to build out the bottoms, and finally cap the cells on the sides next above, giving the lower part of the comb an appearance not at all attractive.

I am sure I have struck upon something good in a bottom-starter fastener, and it costs nothing save a little ingenuity in applying it to the foundation-fastener already in use. For full description see page 552 of the May 15th issue for 1905.

For four or five years I have been using, in a limited way, the plan of producing both comb and extracted honey on the same hive, in the same super, and at the same time. Small cleats,  $\frac{1}{4}$  inch thick by  $\frac{1}{2}$  inch wide and 4 inches long, are nailed on the inside ends of a ten-frame super, at such point as will admit two thin wedging boards, and five section-holders with separators. The super will then be ready for 20 sections and two extracting-frames, one on each side. This does away entirely with those outside unfinished sections so often found when one is working for a fancy grade of comb honey. The sections should be removed as soon as fully completed, and the unfinished ones put together in two or three grades, placed in these comb and extracting supers, and put over a strong colony to be finished as quick-

ly as possible. I like to take off all sections at the close of the white-clover honey-flow and extract all sections not over one-half or two-thirds full, and feed it back to the colonies on which the sections nearly finished have been congregated. Some uncapping might be done to advantage before placing these sections back on the hives to be sure of having all the combs down to one level.

Hull, Iowa.

[We believe our correspondent is right in using extra-thin instead of thin foundation. The less of midrib we have in our comb honey the better.—ED.]

## EIGHT QUEENS IN ONE BOX HIVE.

### How the Bees Keep the Queens Apart.

BY M. D. TYLER.

Last spring a neighbor asked me to see to his bees, as he had two swarms that came from one hive. He had put them into boxes, and had nailed them up so that they could not get out. He wanted me to transfer them into new hives. He also wanted me to see to the old colony, which was in a two-story hive. This last was full of bees and brood to the top, and yet the hive had but three frames in it. It was hard to get the hive apart, and then fit the combs in frames, but I did. In taking out the combs I discovered two queens on one card of brood, so I set that comb to one side and watched them while I worked. I soon discovered two more queens, and I put a couple of them in a tumbler so I could take them home. It was not half a minute before one of those queens was killed by the other. This goes to show that the workers keep the queens apart. If the bees are taken off from a card of brood, leaving the queens alone, they will come together like two bulldogs, and fight to the death. It takes only a quarter of a minute. When I cleaned out the upper story I found two more queens, which, with the two that swarmed out the day before, made eight laying queens in the one hive.

It is all "bosh" to think that two queens can exist in one hive in peace unless they are protected by the bees or by some other means. It is the workers that keep the queens apart.

I have worked with bees for sixty years. A few years ago I transferred 400 colonies for farmers from old box hives into new ones in one season. I think I am the champion transferer.

Seville, O.

[Our correspondent is a veteran in the business of selling honey. He is never so delighted as when he can get a crowd of men to arguing with him and asking him questions about bees, for he says at such a time he always manages to sell a good lot of honey to each one.

It is a good plan for one who understands transferring to make a business of doing it for his neighbors who may not have had much experience.—ED.]

## EXTRACTED-HONEY PRODUCTION.

### The Locality and Methods Whereby Large Quantities of a Superior Article may be Secured in a Leisurely Fashion at a Low Cost; How to Choose a Raspberry Location.

BY W. Z. HUTCHINSON.

[A short time ago Mr. W. Z. Hutchinson, editor of the *Bee-keepers' Review*, while visiting us, asked if we would like to get a series of articles detailing his experience in producing extracted honey in Northern Michigan. He added that he had secured a large number of fine photos, and if we cared to have the set he would go to work immediately on the copy and submit it for our approval. He remarked that, while it might seem a little odd, perhaps, for the editor of one paper to write for another, yet, owing to a lack of space in his own journal, he had been able to give only a brief account of his work, and he thought that perhaps GLEANINGS would like a more complete write-up, brought clear up to date. We assured him that we should be most happy to have him furnish us the manuscript and the photos, as we were sure the former would be very interesting reading; and the latter—well, the editor of the *Bee-keepers' Review* knows how to make them. The articles have been received, and, as might be expected, they are interesting as well as valuable—"good stuff" a newspaper editor would say. We take pleasure, therefore, in presenting the first installment.

The photos in this issue represent, apparently, only a dreary waste—briers and dead trees—indicative of the fact that many a desert or bleak mountain-side contains, buried beneath it, untold wealth. In this case the wealth is in sight, but it takes a trained eye to see it. There are thousands of places in the United States to-day which are supposed to be only barren wastes, useful neither to man nor beast. But how often have we seen those same wastes yield up their treasures (honey) to some bright genius who had eyes to see what others could not. Mr. Hutchinson tells how to judge a raspberry location.—ED.]

The time was when extracted honey was of slow sale at a low price. It may not be worth while here to discuss the reasons *why*, but we can all rejoice in the *fact* that extracted honey has become a staple product, with sure and quick sales at a fair price. With the right kind of locality, sufficient number of colonies, and the adoption of proper methods, an experienced bee-keeper can make a good living—yes, more than that—put money in the bank by producing extracted honey and nothing else.

Every successful bee-keeper eventually develops a system peculiarly fitted to himself and his environments. While I have been managing out-apiaries and producing honey on a large scale for only two years, I have developed a system that seems to me unusually good—one that might be followed with profit in many parts of the country. I have written about it in the *Review* in a desultory way, but now I propose to put it together in a consecutive way, and lay it before the larger class of readers that I can reach through these columns.

### FINDING THE LOCATION—SOMETHING ABOUT NORTHERN MICHIGAN.

The foundation of success in bee-keeping specialty is the location. Unless a man has the proper location he had better relinquish bee-keeping as a specialty or else seek the right location. I did the latter. I went to the wild red-raspberry region of Northern Michigan. I think I can safely say that the

wild raspberry never fails to produce honey. It does not winter kill, as does the clover, and its nectar-yielding properties are less affected by the weather. I have seen bees doing quite well working upon it when the weather was so cool that clover would not yield a drop. I have seen the bees continue to work on berries when it was raining quite a little, and had been raining some time. Many of the blossoms are inverted, like little umbrellas, and the water does not get into them.

It might not be worth while to devote so much space to the raspberry regions were it not that new tracts are being continually logged off, thus offering new pastures to new comers. That many are interested in this region, and would gladly go there to take up bee-keeping as a specialty, I know from the numerous letters that come to me asking in regard to the prospects, where to go to find locations, how to find them, etc. To help a man find a good location, where the nectar is never-failing, and he can spread out and establish out-apiaries, and make some money and enjoy life, is fully as important as to show him how to manage his bees after he is rightly located, hence the following paragraphs.

#### SOME VITAL POINTS IN SELECTING A LOCATION IN NORTHERN MICHIGAN.

Let no one imagine that *all* of Northern Michigan is covered with raspberries, the same as some other portions are covered with clover. This portion of Michigan is laid off in "streaks," so far as timber and

soil are concerned. Pine barrens form a large share of this northern country; and more dreary, desolate, God-forsaken spots it has never been my lot to behold—nothing left but pine stumps and logs blackened by fire; and yet, in spite of it all, there is a sort of weird, lonely fascination about these pine plains. Occasionally there is an old pinery upon which raspberries grow, but they are short, stunted, and scattering, and of little value as honey-producers.

FIG. 1.—HARD-MAPLE FORESTS OF NORTHERN MICHIGAN.

As fast as the timber is lumbered off, red raspberries spring up in myriads, furnishing bee pasturage that is simply incomparable.

After driving for miles through a dreary waste of sand, pine stumps, and logs, there will come a change, sometimes within a few rods, to the most magnificent forest of beech, maple, elm, etc.; and it is in these hard-timbered belts that we must look for the honey-yielding berries. When these tracts of hard

timber have been lumbered off, there springs up a growth of the wild red raspberry that is simply incomparable as a honey-producer.

Having found such a hard-timbered tract, there are several points to be considered in the selection of a site for an apiary. First, an old-settled country is of no value unless lumbering is going on in that neighborhood,

because the farmers cut the timber off slick and clean, and plow up the ground. Of course, there will be a fringe of berries around the edges of clearings, along fences, etc., and a few colonies would probably find plenty of honey; but the man who is going to bring in several hundreds of colonies must find some place back away from the cleared

FIG. 2.—THE WILD RED RASPBERRY IN ALL ITS GLORY.

The timber has been lumbered off, or cut for furnace wood, and the berries have completely covered the ground.

land; or, at least, where the hard timber has not been lumbered off, and has not yet been sold for farms.

Still another point: it is not until land has been lumbered some two or three years that the berries are sufficient in number or growth to be valuable as honey-producers.

If fire runs through and burns up the berries they seldom come in again and grow so rank as when the brush, tree-tops, logs, etc., acted as a sort of mulch. After the sawlogs have been cut on a tract, there is more or less small timber left, and this shades the ground to a great extent, and greatly improves the raspberry pasturage — promotes a more rank growth, and prolongs the time of bloom. Let the location be what it may, it is only a question of time when the undergrowth will come up and run out the berries.

It will be seen that raspberries are not a permanent source of supply, like clover. A large share of Northern Michigan is still covered with hard timber, but it is being lumbered off at a great rate, and a man located there would be able, by shifting about, to have apiaries in exactly the right kind of locations. I have seen locations that have passed their prime, others that were right in their "glory," so to

FIG. 3.—EXCELLENT RASPBERRY PASTURAGE.

This area has not been burned over; scattering trees furnishing shade, and logs and brush act as a mulch.

FIG. 4.—POOR RASPBERRY PASTURAGE.

The ground has been burned over—no shade.

speak, and still others that were lumbered off only last winter. In some parts of Northern Michigan, lumbermen put out systems of narrow-gauge railroads, with numerous branches, in the hard-timbered districts, and all along these roads are choppings of different degrees of "ripeness."

But these choppings are back away from civilization, and the only buildings that are available are log shanties at deserted lumber-camps, most of which have been robbed of their roofs for the sake of getting the lumber. The man who goes into Northern Michigan to produce raspberry honey must expect to "rough it" to some extent, and

A GLIMPSE OF THE FIVE ACRES OF CELERY NEAR BRADENTOWN, FLORIDA, GROWN THE FIRST YEAR ON WILD LAND; THE OWNER, MR. C. L. LATIMER, REFUSED \$5000 FOR THE CROP JUST BEFORE HARVESTING.

live in a shanty, unless he buys or builds a good house; and this is something he ought not to do until he has been there a year or two, and become familiar with the country, so as to choose wisely in reference to future pasturage.

As I have already said, the foundation of all is the *location*—one with an abundance of berries, and around this must cluster all of the other conditions. The most desirable pasture may not be the most desirable place in which to live; but I doubt if any location will be so inaccessible that the bee-keeper won't be able to get his honey out to market if he secures a crop. On the other hand, this new country has its compensations: The streams are all stocked with speckled trout; the pine barrens are often purple with the ripening huckleberries; in August and September a man can eat his fill three times a day of the great, luscious, shining, spicy wild blackberries that have grown in the shade; he can tap the giant maples and make sugar in the spring; he can rejoice in a wood fire simply by cutting the wood; and, if inclined to be a sportsman, he will find plenty of opportunity for hunting or trapping. To the right man, there is a fascination about a region where still lingers some of Nature's wildness.

But, to return: How can a man find a desirable location? This is the question that is

asked me the most often of any. There is only one way, and that is to go into this region and *hunt for it*. Very little can be depended upon what settlers say, unless they are bee-keepers, as they seem to have no conception of what is needed. To illustrate: One man who had lived in that part of the State several years told my brother and myself, with great enthusiasm, of a tract, on the banks of the Manistee, where, for miles and miles, there was a perfect sea of raspberries. As it happened, we had that day driven through that *very spot*. The ground had been burned over, and, while there was quite a dense growth, it was mostly blackberries, with an occasional patch of short, scattering raspberries. We were disappointed so many times, after driving miles to see some promised land, that we ceased to put any dependence whatever upon what somebody told us. As I have said, these men are not bee-keepers, and don't understand all of the points as I have given them in these pages, and are almost certain to be misled.

The best time to look for a raspberry location is in the spring, after the snow has gone, and before the trees and bushes have put forth their leaves. The berry-canescans have a ruddy, brown, or purple color, very easily distinguished, at a long distance, from other brush. After the berries and other bushes

HARVESTING THE CROP AND CRATING IT UP READY TO BE SHIPPED TO NORTHERN CITIES.  
SEE PAGE 511, LAST ISSUE.

have put on their robes of green, all look alike at even a few rods.

*To be continued.*

### SWARMING.

**Some Instances to Show that Bees Often  
Select a New Location Before Leaving  
the Hive.**

BY L. B. SMITH.

We have had it proven to our own satisfaction many times that bees often select a location before swarming. Away back in the 80's, we were in the woods and saw bees going in and out of a knot-hole some 15 feet up in a tree. My first thought was that I had found a bee-tree. After observing more closely I discovered that it was only bees out selecting a place for their future home, for there were more or less bees around all the trees near that showed any signs of being hollow. From their actions it was easy to see they were searching for a cavity for their future home. I watched them with much interest for several hours toward the middle of the day; but they seemed to pay little attention to any of the trees except the first one mentioned. Around this they greatly increased in numbers until it almost seemed as if a small swarm were in and around this tree. During the time, I went to the house

and told my wife to keep a close watch on a certain colony I knew was preparing to swarm. I was sure they were my bees that were so busily engaged at this tree. Pretty soon I heard my wife calling, "The bees are swarming!" I noticed, however, the bees about the tree had become very much less in numbers. A very few were to be seen at the tree just then.

I hastened to the house to watch the swarm to see what the result would be. They were pretty well out of the hive when I reached the house, and had started to cluster. Not over two-thirds of the swarm ever clustered at all when they broke cluster and made a direct line for the tree where I had been watching them for hours, and went directly into it.

At another time a neighbor called on me, saying he had found a bee-tree, and wanted to save the bees. They were working strong, as he thought. After a good many hard blows with his ax he felled the tree, and, to his utter astonishment, no bees were in it, and no signs of comb or any thing that showed that bees had ever occupied the tree. Before long he saw a big negro coming on a dead run through the brush, rattling a bell for all it was worth; and about the same time, he heard the roaring of a swarm of bees, and very soon they were hovering about the spot where the tree had stood. After circling around for a short time the bees

HAND-CAR FOR MOVING EXTRACTING-COMBS INTO THE HONEY-HOUSE.

clustered on a bush near where the tree stood, perhaps much astonished because their newly found home was destroyed.

These, with many other instances I could relate, convince me that bees often select a home before they swarm. I do not make the claim that they always do.

Rescue, Texas.

### A HAND-CAR IN AN APIARY.

How to Move Hives and Supplies with the Least Possible Amount of Labor.

BY F. H. CYRENIUS.

The engraving shows a quick method of transporting hives, supers, etc., to and from the honey-house. The hives must occupy a narrow space about 15×100 ft., through the center of which runs a wooden track. The car holds six hives on the platform, and as many more piled on top as desired.

In extracting honey and taking off supers a sheet or spread that covers up the whole load is used to prevent robbing. The tracks are so arranged that the car runs directly into the house, where the load is uncovered and removed to suit convenience. I find this is a great labor-saver.

Oswego, N. Y.

[Our older readers who joined the GLEANINGS family about the time it first started will recall that A. I. Root, in his first bee-yard from which he gleaned the inspiration to start this journal, had a short railway running through it like this. We can subscribe to all the statements made by our correspondent. This arrangement ought not to be very expensive, with the exception, perhaps, of the car. But if light cast-iron wheels were made at a foundry, the rest of the car could be assembled from picked-up material, with the help,

possibly, of a blacksmith if necessary.

The track would be a simple affair. Hardwood rails could be used, made from well-dried timber that would not warp, and tied together at intervals. If made in sections, the location of the track could be easily changed, or the whole thing taken up at the end of the season and stored away in some sheltered place until the following spring.—Ed.]

### A SWARM LATE IN THE FALL THAT BUILT COMB IN THE OPEN AIR.

BY A. D. STONEMAN.

This swarm of bees was discovered late in the fall, alighting on the limb of a pine-tree. Some two weeks after that they were still there, as this picture shows. The combs were built 30 feet from the ground, on quite a large limb, and about 15 or 18 feet from the body of the tree. On quite a cool frosty morning I got an extension ladder, and, with the help of my boy, put it in position, tying the top securely. Then with my smoker in one hand and a saw in the other I went up. It was ticklish business standing on the two top rounds, and trying to do any thing; but I found that the bees were very quiet, so I did not use the smoker. The bees were located on the limb where half a dozen small

limbs branched out, so by holding on to the big limb with my left hand I sawed off all the small ones; then taking hold of one of the ends of the small limbs with my right hand I sawed the large limb off with my left. By this time I had shaken the bees up pretty well, and many of them were flying around quite lively; but I held the branch at arm's length until they were all clustered again, and then started down, arriving at the bottom safely. I had to carry them about a quarter of a mile right through town, and every one who saw me coming with those bees got out of the way. I told them, however, that I had the bees hypnotized so that they would sting no one, and they did not.

When I reached home I got an empty hive and put them in it; but as the limbs were not cut short enough I had to let them rest on the edge of the hive, for by that time the weather was getting quite warm, and the bees were getting uneasy. I laid an oilcloth over them until the next morning, when I sawed the limbs off so that I could hang them in the hive by nailing two small cleats on the side. They would have been short of feed, as they had but very little honey, so I fed them syrup made of candy and sugar. To-day I have them in the cellar all right, as I put them in before the weather became too cold.

Quasqueton, Iowa, Jan. 1.

## BREEDING OF QUEENS.

**Queens from Swarm Cells Perpetuate Swarming; Cells should be Cared for by a Strong Colony; a Colony Long Queenless Stores Much Pollen in Brood-frames.**

BY WM. H. LONGSDORF.

I for one can most heartily indorse Mr. Alexander's recommendation to rear queens from a queen-mother only at a time when she is not under the swarming impulse, page 209. However, I want the queen larvae *fed and cared for* in a colony that is as nearly in a swarming condition as possible—that is, with an abundance of bees, a good supply of sealed brood and honey, a comparatively small amount of unsealed larvae and eggs, and a somewhat crowded condition. I use a single queen-excluding division-board in the brood-chamber, with the queen-cells on one side, and queen, preferably an old one, on the other. Queenless bees are not so good for rearing queens, as they are usually very poor feeders and will nearly always select a few cells for feeding, and somewhat neglect the others, producing many poor queens.

I have reared nearly all of my queens for the last ten years from selected queen mothers on the Doolittle plan. I did it at first for the simple purpose of getting my bees Italianized by buying a select queen and rearing

all my queens from her, the next year doing the same; and then not being satisfied with the qualities of all my bees I selected from the best for breeders, rearing all my queens from them. I found so many advantages in this plan that I have followed it up to the present.

But for a considerable time I did not think of what influence this method might have on their swarming propensity. I soon began to notice, however, that the colonies that swarmed with the hive only half full of bees and

COMB BUILT IN THE OPEN AIR LATE IN THE FALL.

The swarm alighted on a limb of a pine-tree and built comb, even though the weather was beginning to get cold. One piece of comb broke off before the picture was taken, so it was laid on top.

brood, and refused to yield to my usual methods to prevent persistent swarming, were those that had managed in some way to rear their own queen from swarming-cells. With my methods these colonies are easily located, as I nearly always introduce laying queens to queenless colonies and those which have cast a swarm; and the laying queens are always clipped before introduction. If a virgin is introduced the records show it.

One of the first things to show after using select queens only, for breeders, is the more uniform color of the drones and gentleness in the bees as Mr. Alexander has said. Good wintering qualities I also attribute in part to the quieter disposition of bees from queens reared from non-swarming mothers, and also from the fact that I do not allow the bees to remain without a laying queen long enough to get the brood-frames filled up with pollen and honey, and *sealed up*. This is quite sure to cause trouble in wintering, and also spoils the comb honey produced on the hive after the queen commences to lay, by having the cappings removed and built into the new comb in the sections, and the honey filled behind it. This will not be the case if the honey in the brood-combs is not yet sealed over. The honey will be carried up, and new comb built, and it will be as nice as though built over new brood-combs, no matter how old or black the brood-combs may be.

Another important consideration in the control of swarming is prolific queens which will produce large strong colonies; for it is the medium-sized colonies that are the most likely to swarm—those that will just barely fill the brood-chamber at the time they get it filled with brood and honey. A strong colony will have a large force to put into the supers as soon as the honey comes in, and will clean the honey out of the brood-combs so the queen will have plenty of room. I have very frequently had colonies produce from five to six ten-frame-hive comb-supers with-

REMOVING HONEY FROM THE ROOF OF A BUILDING.

out trying to swarm. I rear queens for my own use only, and not to sell.

Arkansaw, Wis.

## REMOVING HONEY FROM THE ROOF OF A BUILDING.

BY M. L. BREWER.

In the footnote to my article, p. 1326, Oct. 15, you speak of the use of the bee-escape to trap the bees out and into a hive, the entrance of which is close by. The entrances to the cavities are almost universally in such places as would make it next to impossible to station a hive, as the accompanying illustration will show. Four days ago, Oct. 14, I removed the shingles that I relaid at the visit described in the article referred to, and duplicated the former amount, or better. Only the upper part of the wagon shows in

the picture, the high boards on the opposite side being used as a support for the ladder.

I always use a long apron to protect my clothing from getting smeared with the honey, and in it are pockets for my tools and supplies, such as hammer, chisel, putty-knife (which is indispensable), matches, and extra smoker fuel. The smoker and dishpan are visible, with honey showing in the pan.

This same pan (and a large one it is), with a good-sized butter-bowl and a large meat-platter were all rounded full of honey, with enough left to fill a medium breadpan.

The entrance was under the shingles just at the drip to the water-lead. Such work is hard, and straining on the muscles, and is done only by a crank of all cranks — a bee-crank.

Philo, Ill.

### THE BEE-MOTH.

#### Their Ravages and their Eradication by Means of the Deadly Cyanide of Potassium.

BY PROF. H. A. SURFACE,  
*State Zoologist of Pennsylvania.*

To many bee-keepers the bee-moth is known as the worst enemy. Perhaps we should say the bee-moths, because there are two species of these pests, the one of which is not half the size of the other, and is consequently known as the lesser wax-moth or lesser bee-moth. Practically all bee-keepers know that in the worm (or larval) stage these pests bore through the honey-comb, devouring it, living within the tubular silken cases, and often eating away the capping or waxy covering of the young bees in the comb in such a way as to uncap them and leave rows of young bees with their heads visible in the cells. This is one of the causes of what is sometimes known as "bald-headed brood." There are other causes of this, such as chilling or insufficient food; but the larva of the bee-moth is one of the chief. When this pest becomes grown it crawls into some protected spot, covers itself with a silken cocoon, and in the course of a few days (depending upon the temperature) transforms into a winged moth, commonly known as a "miller," and enters the hives or sections of honey-comb at any possible place, seeking comb on which to lay its eggs. In the course of a few days these eggs hatch, and the larva or worm repeats the life cycle.

The best possible treatment for the bee-moth in the hive is to keep in the hive a full and strong strain or race of bees that will look after the moth and clean out the worms if these should start. Moths always attack weak hives in preference to strong. It is important that the entrance of the hive be not too large, especially at night, when the winged moth is flying, to be properly guarded by the bees. It is likewise important that there be no fragments of comb around the entrance of the hive to attract the moths in unusual numbers. All fragments or pieces

of comb, however large or small, should be gathered into a receptacle for the purpose, and kept so tightly closed that no insect can enter it. As often as once a week, during the summer, melt all rejected pieces of comb into beeswax. Leave no deserted hive with comb for the moth to inhabit and become a source of infestation to the entire apiary. When combs are to be stored it is a good plan to put them into an empty hive-body and place this above a strong colony of bees or close it so tightly with strips of paper pasted over the cracks that even an ant can not enter.

The best possible means of avoiding the ravages of the bee-moth is by fumigation. We have recently had occasion to fumigate combs and honey. This produced no evil effects whatever, and certainly killed every bee-moth in all its stages, whether it was an egg, a larva, a pupa, or a winged moth. This fumigation is possible in the hands of a novice; but he should be very careful to follow instructions. Place all honey and comb, supposed to be infested, in a room, box, barrel, or bin that is air-tight. Determine the cubic contents of this vessel by multiplying its length, breadth, and height, and for each 100 cubic feet of space use the following formula: Cyanide of potassium, 98 per cent pure; 1 ounce (by weight); sulphuric acid, 1.83 specific gravity, 2 ounces (by liquid measure); water, 4 ounces (by liquid measure).

Compute and weigh or measure the amount of material to be used. The cyanide of potassium is sold in hard white lumps resembling alum. Determine the amount of this to be used in the vessel or room which is to be fumigated. Put the proper amount into a paper sack and put it on a stand or on the floor near the vessel which is to hold the liquids. Put a stone jar on the floor in the middle of the room or vessel, using one that is at least twice or thrice as large as will be necessary to hold the liquids that are to be placed in it. Into this jar pour four liquid ounces of water, or one-fourth pint for each one hundred cubic feet of space to be fumigated. Into the water pour two ounces of sulphuric acid for each one hundred cubic feet, or half as much of this as of the water. Both acid and water should be measured by the liquid measure rather than by weight. It is important that the acid be the thick or strong sulphuric acid, sold commercially with a specific gravity of 1.83 per cent. Drop into the acid and water the paper sack containing the cyanide of potassium, and close the vessel or room instantly. Do not remain a fraction of a second in the room or bin after the cyanide is dropped into the acid and water. There is no danger whatever until this combination is made; but as soon as this is done, fumes are given off which are deadly and instantly poisonous to all insects and higher forms of animal life, as well as to delicate plants, but will not injure metal work, varnish, cloth fabrics, seeds, nor food products of any kind. Honey is not tainted nor poisoned by being fumigated by this material, as we proved by several ex-

periments last summer. If there be domesticated animals of any kind in or adjacent to the room in which the fumigation is to take place they should be removed before it is undertaken. Also the first step in this process should be to see that all windows and doors, excepting the one through which the operator is to escape, are made airtight, and that all cracks are stopped tightly with wet paper. Preliminary arrangements should be made for tightly closing all crevices in the vessel or room in which the fumigation is to be made, if this be not a box or barrel. A large hoghead is excellent for this process, and it is sufficient to have two wet blankets present and spread them over the vessel, having boards ready to lay on top of the blankets to hold them in place. All arrangements for closing the vessel or room should be made before the cyanide is dropped into the acid.

This cyanide is the deadly prussic acid of which many have heard, and the fumes of which are known as hydrocyanic-acid gas. If the fumigation be in a room in which any article is forgotten, let it alone. Do not enter for two hours, after which time air the room properly by opening from the outside before entering it, because to enter the room before it has been properly ventilated or aired, or to fill the lungs once with the deadly gas, would mean instant death; but at the same time this is no reason why any intelligent person should not avail himself of the benefits of it. Let the vessel or room remain tightly closed for at least two hours or longer, and then open it and give it an opportunity to become well aired before entering it for further work. If comb or honey be stored in close hives, supers, or vessels a room to be fumigated, these hives or supers should be opened before fumigation so that the deadly gas can penetrate them and kill the pests.

After having fumigated comb or honey in this way, the material can be stored in any tightly closed vessel, such as a box or empty hive-body, and can be kept for an indefinite length of time, even for years, without being attacked by the bee-worm or bee-moth, if tightly closed. It is important in storing, first, that the worms and eggs be killed by the fumigation; and, second, that they be stored in vessels that are so tightly closed as to prevent the moth from entering and laying its eggs. Remember that the lesser bee-moth is a very small individual, and can go through a small crack. Strips of paper should be pasted over cracks in boxes, hives, and supers, if piled upon one another, generally fit together so tightly that no special provision for sealing the cracks between them is necessary. Common window-screen wire is sufficient protection to comb or honey from the attacks of the bee-moths as long as may be needed. The advantage of this method of fumigation over the old-fashioned process of "sulphuring" is the ease, rapidity, and absence of danger of fire. The evil effects of inhaling the gas can be avoided with less trouble than would be necessary in avoiding fire from the burning sulphur. We repeat

the statement, that honey is not injured in flavor, color, nor otherwise, by this fumigation process. We have tried it several times. Harrisburg, Pa.

### SPRING FEEDING.

#### The Opinions of Some of the Authors of Text-books on the Subject; Feeding for Stimulating in the Spring Considered Profitable.

BY E. W. ALEXANDER.

As I happen to be a defendant in this matter of spring feeding, as given in the March 1st and April 15th GLEANINGS, I feel it a duty I owe to myself and friends to call the attention of the readers of this journal to a few established facts along this line. We will now go to our text-books and see what they say on this subject. I will endeavor to be as brief as possible.

Commencing with Prof. Cook's Manual of the Apiary, turn to page 159, where he, in speaking of stimulative feeding, says, "As already stated, it is only when the worker bees are storing that the queen deposits to the full extent of her capability, and that brood-rearing is at its height. In fact, when storing ceases, general indolence characterizes the hive; hence if we would achieve the best success we must keep the workers active, even before gathering commences, as also in the interims of honey-secretion by the flowers; and to do this we must feed sparingly before the advent of bloom in the spring, and whenever the neuters are forced to idleness during any part of the season by the absence of honey-producing flowers. For a number of years I have tried experiments in this direction by feeding a portion of my colonies early in the season, and in the intervals of honey-gathering, and always with marked results in favor of the practice. Every apiarist—whether novice or veteran, will receive ample reward by practicing stimulative feeding early in the season, then his hives at dawn of the white-clover era will be redundant with bees well filled with brood, and in just the trim to receive a bountiful harvest of this most delicious nectar."

Now we will see what A. I. Root says upon this subject. We will take the first edition of his A B C of Bee Culture, and turn to page 75. Where he speaks of a drouth cutting short the supply of nectar he says: "Many of the queens stopped laying entirely. At this stage a little feed during the night would start the queens laying wonderfully, and the fed colony would rush to the fields for pollen in a way that demonstrated at once that feeding at such a time was a very profitable investment if one wished to build up weak stocks and nuclei. A stock that had been fed a half-teacupful only would go out for pollen an hour earlier than the others, and would bring in double the quantity. A still smaller quantity will set them to building out foundation most beautifully; and I never in my life saw the work in the hive go on so

satisfactorily as it did during the hot dry dusty days under the influence of a very moderate amount of feeding during the night."

And then, again, on page 77, he says, "And after feeding perhaps a ton of the grape sugar I am prepared to say that it is a decided success for stimulating brood-rearing, for rearing queens, and building up colonies."

We will now take the late Henry Alley's Bee-keeper's Handy Book and see on p. 107 what he said in regard to stimulative feeding:

"When a colony is being fed, the queen commences to deposit eggs more vigorously, and the colony exhibits greater activity than its neighbors that are not stimulated. Feeding for this purpose should not be resorted to until the bees commence to carry in pollen as the effect of the increased activity prior to this time would be injurious. The proper time is to feed at night, and not over half a pound of food should be given at any one time unless the bees are short of stores, and it should be discontinued when honey can be gathered from natural sources. Food for stimulating should be made quite thin with water, say six pounds of sugar and five pints of water, and a small amount of honey to flavor. The water will be utilized by the bees in brood-rearing."

I should advise making the syrup more than half water. I should like also to call your attention to the latest edition of the A B C and X Y Z of Bee Culture, and see what is there said on this subject; and right here let me say that this edition to our bee literature is worth far more than its cost, and should be in the hands of every honey-producer in the land. On page 200 the authors say:

"In getting colonies up to good strength to gather the honey harvest, or induce nuclei, or full colonies for that matter, to cells for the purpose of queen-rearing, the daily feeding of half a pint of syrup should be practiced."

They also say on page 203, in speaking of H. R. Boardman, of East Townsend, Ohio, that he practices a plan which often insures a crop of honey even during poor seasons. "In brief it is this: He feeds all his colonies as soon as it becomes settled warm weather, whether they need stores or not. The syrup is given them slowly to stimulate brood-rearing. This feeding is continued clear on to the honey-flow, when, of course, it is discontinued. The result is that the hives are overflowing with bees and brood."

Then still further on the author says, "While it costs considerable to feed bees in this way I believe Mr. Boardman's experience has been such that he feels warranted in continuing it; and then if the year proves to be a good one he will get a tremendous crop of honey. One year when I visited him he had secured a fair-sized yield from each colony, and a poor year at that, while his neighbors round about him did not get any surplus, and all they did get was brood-nestfuls of honey and nothing more."

Father Quinby and his son-in-law, L. C.

Root, many years ago were the first to call my attention to the value of stimulative feeding in the spring. They were very enthusiastic on the subject, and advised me to practice it every spring if I expected to make an early increase or secure a nice surplus of clover honey. I think you will find in Quinby's book, "Mysteries of Bee-keeping Explained," something on this subject. I have lost the copy I once had, and therefore can not quote his words. And now while I am in company with these shining lights of apiculture that I have just quoted above, I wish to be put on record as saying that I have practiced spring feeding for over 30 years, and during that period I have fed at least 5000 colonies for the purpose of promoting brood-rearing during the spring, and I am sure that, all things considered, it has been one of the most useful and profitable things I have ever done in the apiary.

As the defendant in this case, I now submit it to the 50,000 readers of GLEANINGS as a jury to decide whether I have or have not produced sufficient evidence to sustain the position I have always taken. I might continue, and produce volumes of testimony to prove that I am in the right on this subject Delanson, N. Y.

[We are not sure that our correspondent has quite understood the point of view of his critics; and in a like manner we may assume that they may not have understood him. As we understand it, they are not arguing that bees should never be fed in the spring to stimulate brood-rearing; but they are contending that, if feeding is necessary *some time within the year* the bees should be fed in the fall, and enough so they will have plenty of stores clear up to and during settled warm weather. Or, to put it another way, it is not a question with them whether bees need to be fed in localities where natural supplies are deficient, but the time *when* feed should be given.

The text book authorities referred to, so far as we can see, were not arguing that bees should be fed in the spring rather than in the fall, or that they should be fed in the fall sufficient to bring them to early spring feeding, but to show *how* to stimulate brood-rearing in early spring when the colonies are weak or short of stores. It is true some of them advise spring feeding; but a text-book can never quite keep up with modern teachings in a journal; the old editions of works of ten or twenty years ago much less so.

Mr. H. R. Boardman's method of feeding before the honey-flow, as we understand it, had in view the jamming of the brood-nest with brood and honey, in warm weather and just before the honey-flow began, so there would be no place for the storage of the nectar except in the supers. His plan would not necessarily be out of harmony with the notions of the opponents of spring feeding, for it was for a different object—leaving no room for honey except in the supers.

It is perhaps well to bear in mind that they were speaking from the standpoint of

the honey-producer where the main honey-flow comes on the last of June or first of July. Mr. Alexander's locality does not have its main flow until some weeks later. During the long period of warm weather before the buckwheat comes into bloom, there would necessarily be a large amount of brood-rearing, and it is probable that no amount of heavy feeding in the fall would give the bees all the stores they require until the buckwheat opened up. Here is, obviously, a condition very different from that spoken of in the articles by the anti-spring-feeder people.

This whole matter really resolves itself down to this: Spring feeding is really a question of locality. Alexander is right in advising and practicing spring feeding for a locality with a late flow like his. No one who has seen the big populous colonies he has, and the big crops of honey he secures, can really call in question his methods for *his conditions*; for the proof of the pudding is in the eating.

In Europe, spring feeding is not advised. When practiced it is called *speculative feeding* because it is problematical whether it will pay or not.—ED.]

## THE EVOLUTION OF HIVES.

BY W. K. MORRISON.

The first real effort to improve hives was probably the Greek flower-pot hive with bars across it, for the bees to attach their combs to. To make the roof movable, and also to

HUBER'S EXPERIMENT HIVE.

provide parallel bars for the combs, was quite a step in advance over the crude cylindrical hive of the Egyptians, though it is quite possible the latter were the inventors of the bar hive, and the Greeks only copyists. It is ev-

ident, from all we know, that the Greeks were well informed in bee culture before the Christian era; but it may be they borrowed their knowledge from the Egyptians, as many others did. It would not do us much good now if we did know who invented the bar hive. In any event, it was in actual use all through the Dark Ages down to the time when the celebrated Della Rocca resurrected it in the islands of the Egean Sea, and called attention to its merits.

Maraldi, the Italian scientist, was the originator of the one-comb-at-a-time idea, for he

HUBER'S LEAF HIVE, ARRANGED FOR MAKING INCREASE.

was the inventor of the observatory hive. He placed a comb between two large glass plates, so that he might be the better able to watch their movements. He did not comprehend the value of a bee-space, and consequently he got the glass plates too far apart the get the best results. In the Maraldi hive the bees very frequently built the combs crosswise. This did not do any material harm, as it is actually easier to see what the bees are doing, particularly in the cells, when the combs are placed across instead of longitudinally. Maraldi, by his invention, gave a great impetus to the study of the honey-bee, and laid the foundation for greater things yet to come. Réaumur made great use of Maraldi's invention, but we do not know just how he made his discoveries. He made a great advance in our knowledge of bees, more particularly as regards what their habits are while in the hive.

Huber followed in Réaumur's footsteps and made great use of the observation hive. He complained of the bees building the combs crosswise of the hive, and he soon saw the necessity of narrowing the space. In 1789 he invented a hive in which each comb was constructed in separate frames. His object in doing this was to enable him to take a colony of bees and their combs all to pieces whenever he desired, and also to put it together again when the examination was finished. In doing this he showed a consummate

HOWATSON'S SCOTCH HIVE, 1820.

knowledge of bee architecture, for his top-bars were  $\frac{1}{4}$  inch in width, and the frames were spaced  $1\frac{1}{4}$  inches from center to center.

The Bingham hive belongs to the Huber type; but the Michigan man makes use of the bee-space at top and bottom. The Quinby hive with standing closed-end frames belongs to the Huber type, and so does the Aspinwall, of a later date than any. It has been said by some that hives of this sort are not practical; but as a matter of fact some of the most famous and successful bee-keepers in the world have used just such hives.

Huber's masterly work gained for him the name of being one of the first naturalists of his age, and his letters on bees were translated and published into all western languages of any prominence. Practical bee-keepers were slow to perceive the immense value of Huber's discoveries. He lived, as many able men have done, ahead of his age.

In Great Britain, hive invention took the form of improving the hive of Mewe (1652 A. D.). The idea was to have a movable roof and bars on which to attach the combs. Howatson's hive here shown was invented in Scotland, probably about the year 1820, for his book, which is a remarkably good treatise on bees, was published in 1825, and he speaks as if his hive was no new invention—at least he had given it a fa-

Hives of this kind are known as "Stewarton" hives, and it was by means of these the Scotch bee-keepers swept the English bee-men off their feet at the great bee-keepers' show in the Crystal Palace in 1878. Between the bars are strips of glass to compel the bees to attach the combs to the bars, and also to keep them in their place. A good many of these hives were (and are) octagonal in shape, as more agreeable to the bees. When the Langstroth frame appeared, the Scotch were sharp enough to adapt it to the Stewarton.

The next great bee-hive inventor was the Russian. Prokopovitch, who certainly has great claims for grateful consideration from modern bee-keepers. A glance at the cut on next page will show that the man who invented such a hive knew the requirements of bee-keeping. He had 3000 hives himself, all with bees in them, and he sold quite a number. Besides, he conducted a bee-keepers' school where he turned out a number of successful bee-keepers, skilled in the use of his hives. He was a bee genius of the first rank. Russia being an oriental country, with little intercourse with western nations, Prokopovitch's hive did not become known in Western Europe as it ought to have done according to its merits.

France and Switzerland, owing to the discoveries of Réaumur and Huber, became hotbeds of bee-keeping, and books and inventions followed thick and fast after the demise of Huber. In France, Debeavoy invented a hive in 1845 that came very near depriving Lang-

STEWARTON HIVE OF SCOTLAND, 18TH CENTURY.

stroth of his honors. Here we have the hanging-frame idea, but not the bee-space. Munn, in England, a little later, brought out something similar but lacking practicability.

In 1851 Lorenzo Lorraine Langstroth invented the movable hanging frame with a bee-space on all sides in combination with a movable roof, also having a bee-space on the under side. The United States Patent Office allowed him a broad sweeping patent covering all his rights in the clearest manner; yet all sorts of infringers arose to claim his great invention as theirs. Had Langstroth lived now, and been able to hire good lawyers, he would have been in a position to levy heavy fines for infringements. As it was, he was robbed of the fruits of his invention by persons of unscrupulous tendencies. Others have tried to claim for themselves or their friends the honors of this great invention which rendered the construction of a scientific hive an easy matter. Even Langstroth was himself persuaded that Dr. Dzierzon had discovered the same invention.

Dzierzon himself made no claim to such a thing; in fact, he prided himself on his side-opening bar hives. He cut his combs with a long knife, and then pulled them out with tongs. Americans would have no patience with such a plan. To the day of his death he objected to hives with movable roofs as unsanitary or unhygienic. Berlepsch adopted part of the Langstroth idea by using frames instead of bars; but the tongs are very necessary, even then, in the Berlepsch system. Any one interested in this subject, by studying Dzierzon's and Berlepsch's books, will soon perceive that neither has the slightest claim to the hive having hanging movable

PROKOPOVITSCH'S HIVE, EARLY PART OF THE 19TH CENTURY.

Nederland, Switzerland, Norway, Sweden, Australia, South Africa, all concede Langstroth as the man who solved the hive problem for them. This is due in no small degree to the late Charles Dadant, who at long range fought Langstroth's battles in Europe.

Having right on his side he succeeded in convincing his opponents that Langstroth was the man who solved the hive problem for all mankind.

DEBEAVOY'S HIVE.

frames with a bee-space and movable roof. In addition, one ought to read Langstroth's book, which shows his invention was no accident. On the contrary, he left his German rivals far in the rear in every respect. England, France, Russia, Italy, Spain, Belgium,

### MAKING UP WINTER LOSSES.

#### A Review of Some of the Successful Plans for Making Increase.

BY E. D. TOWNSEND.

[Our correspondent assumes that the reader has a general understanding of both the Somerford and the Alexander plans for making increase, and for this reason he does not go into details in describing them. Any one who desires fuller particulars, however, may find both the Somerford and the Alexander plans in the 1908 edition of the A B C and X Y Z of Bee Culture.—Ed.]

Comb-honey producers may be striving to keep down increase, but extracted-honey men are more interested in plans for making up winter losses; for if their bees are handled as they should be there will not be enough natural swarms to make up for the loss through the year. Each season, therefore, there will be some artificially made swarms, and the purpose of this article is to show how to do this to the best advantage.

There is a rule to be observed in the making of artificial increase that is very important. The brood should be left undisturbed for the first eight days after being made

queenless to allow the bees time to cap all the unsealed brood. This rule or principle is observed in the Somerford, Alexander, and Chapman plans, all of which will be considered here; and if bee-keepers would keep this thought in mind, and work out a system of artificial swarming in which no unsealed brood is carried away from the parent colony, much better success could be expected. It is well known that, when bees are carried to a new location in the process of making artificial increase, if the apiarist is not well versed in the art of making bees stay where they are put in the different manipulations, large quantities of unsealed brood will be lost by the bees deserting the hive in the new quarters and returning to the parent hive. Let us now consider the

#### SOMERFORD PLAN FOR MAKING INCREASE.

This is a good one; but in order to work this system to the best advantage, one ought to have a very good stock of bees. The idea, in brief, is as follows: During either a natural or artificial flow of honey, the queen is removed from a colony that is very strong and in good condition to build queen-cells. In ten days, when the queen-cells are ripe and all the brood sealed, the colony is ready to be divided.

The average bee-keeper will have no trouble with the plan up to the time the division is to be made; but the difficult part comes when the attempt is made to compel the bees to stay in their respective places on the new stands. We will suppose that it is early in the season, and that two frames of brood have been selected with at least one good queen-cell, and that the bees from a third frame have been shaken on to the first two frames. The difficulty now consists in trying to make a good percentage of these bees stay with the brood on the new stand.

In preparing the hive for these little colonies, a lath is nailed over the entrance through which a  $\frac{3}{8}$ -inch hole had previously been bored, which hole, however, is now corked up. The third night after the little swarm is made, and after the bees have stopped flying for the day, this cork should be removed from the  $\frac{3}{8}$ -inch hole at the entrance, when the bees will be found ready to come out; for during the confinement they will have been gnawing at every opening where a particle of light could be seen. On this account, if the entrance were thus opened during the middle of the day, every bee that could fly would rush out and many of them would go back to the old stand, for it would be natural that they should prefer the old home to the prison from which they have just escaped. The consequence would be that but a very small number would be left at this new stand, with about as many bees at the old stand as there were before the division was made. Such a small swarm or nucleus would have a hard slow pull in order to get in shape for winter, and many times it would have to be helped. The small entrance, consisting only of a  $\frac{3}{8}$ -inch hole, and also the time at which this entrance is

opened, makes the plan successful where it otherwise would be uncertain and perhaps an actual failure. For instance, if this  $\frac{3}{8}$ -inch entrance were opened late in the day after the bees had stopped flying, there might be, perhaps, a cupful of bees that would crawl out of the little entrance, for they are quick to realize that they are no longer prisoners, and the glad tidings go through the hive like magic. However, since it is so late that the bees will not fly, there will be practically none that will go back to the old stand. By this time the young queen has hatched, and the bees soon begin to carry out dead bees, etc., and to clean house generally. In other words, things have changed suddenly, for the bees that were prisoners, and were thinking of nothing but trying to get out, now begin to think about keeping house, and during the first night of liberty much is done along this line, so that, when morning comes, and the bees take their first flight, they no longer try to go back to the old location, but mark the new one, so that but very few go back. The consequences are that the nucleus will be in good condition, and very thrifty, when it might otherwise have been almost a failure.

In making nuclei with this Somerford plan we start a few artificial queen-cells at the time of making the divisions, which cells are from our best stock, so that if, for any reason, extra cells are wanted they will be on hand. It sometimes happens that it is convenient to use a colony for increase that we would not care to breed from, and it is less work to make artificial cells than to cut them from one comb and transfer them to another one, as would have to be done if following the Somerford plan, for many times all the desirable cells will be on only one or two combs of brood. Furthermore, only a few of the cells in such colonies will be good enough to use, the inferior ones being torn out when the division is made.

#### HOW THE QUEEN-CELLS ARE PRODUCED.

With the number of colonies that the honey-producer has to select from, there is no trouble in picking out colonies for cell-builders that are especially adapted to the work. I have found that nervous bees are better cell-builders than the more quiet strains, so in selecting the cell-building colonies pick out hybrids or bees that tend toward a darker-colored strain. After making this selection, see that all the cell-building colonies are strong in numbers. Then remove the brood and the queen from each, being sure, however, that there is plenty of honey left. However, it sometimes happens that there is brood in nearly all of the combs so that, when these are taken away from them, there will be almost no honey left, and thus it will be necessary to give two or three frames of stores, filling up the empty space with empty combs with the exception of one or two in the center of the hive. In this space in the center, place bars containing empty cell-cups, in order that these may be cleaned and made ready by the queenless bees for the

larvæ to be transferred later. The first day after the bees have been made broodless and queenless they will be anxious to get brood to start cells with.

We are now ready to transfer the larvæ from some of the best queens to the cells which have been cleaned out by the queenless bees. A transferring-needle, jelly-spoon, plenty of queen-cells containing royal jelly, etc., will be needed. There is enough royal jelly in an ordinary queen-cell to prepare ten cells for larvæ. It is important to get the larvæ transferred to the jelly in the prepared cells so nicely that the bees are hardly able to tell it from their own work. The cell-bars containing the transferred larvæ are now placed in the queenless colony to be started; and after they have been accepted, in a day or two they are taken from the queenless colony and placed in the second story of a powerful colony above a queen-excluder, where they may be finished. Two frames of brood should be lifted up from the lower story, and placed one on each side of the cell-bars in order to make sure that the bees do not leave the cells and go below, which might happen on a cool night. With the two frames of unsealed brood it is quite certain that the cells will be well taken care of. I am sure that the work will succeed better if the cells are started in a queenless colony in the way described, rather than in an upper story over an excluder. Of course, after the cells are started they can be transferred to such an upper story over an excluder to be finished.

For the honey-producer who raises only the queens that he needs to make up winter loss and increase, and when the regular brood-frame is used, no tools except those that I have mentioned will be necessary. These are so few, and their advantages so great, that no one can afford to be without them. In this way a queen can be supplied any time during the season.

#### THE ALEXANDER METHOD OF MAKING INCREASE.

This is a very good system, for, as in the Somerford method, the brood is left with the full force of bees until it is all capped. This, of course, means a saving of all the unsealed brood, and this can not be said of some of the other methods which are being used where the unsealed brood is moved to a new location from which many of the bees that were taken with it go back to the old location, leaving the brood to take care of itself.

With the Alexander plan the queen-cells are all produced artificially, as explained above. By the way, the brood-nest above the excluder is one of the finest places to get cells finished after they have been started in the queenless colony. A ten-day-old cell should be ready to give the brood four days before it is set on the permanent stand. In this way the young queen is ready to fly the first day after the division is made, and she becomes a laying queen in another week.

We made up some winter losses by the Alexander plan of increase just at the com-

mencement of the clover flow. In this case the brood-nests were all ready, some having honey where the bees had died before it was consumed. The queen and one frame of brood were put in the center of one of these sets of brood-combs, and a queen-excluder was put on top; then the brood and bees were set over this so that all were on the old stand. In one week a ripe cell was given the bees in the upper body, and on the eleventh day this upper body was set on a stand of its own with a virgin queen ready to fly the first favorable day. This worked well, for all were in good shape for winter, there being no weak inferior colonies likely to be robbed out at any time. There was one objection, however—the plan was expensive. It can be seen that a set of brood-combs to be filled with brood and honey is equivalent to a set of frames containing the best clover or raspberry honey, and this amount of honey would be worth about \$4.50. It is evident that we could go into the market and buy bees for less money than this.

Our next plan was to wait until near the close of the clover season, when the honey-flow would last but a few days longer, it having already begun to slacken. At this time the plan just described was carried out, and it worked better, for it gave the advantage of the honey-flow in which to have the cells prepared and introduced, and it allowed also the colonies to get in a little honey so that they would be in very good shape, but of course short of stores, although they usually would have enough to last them until the time to feed up with sugar syrup for winter.

While some of our winter loss is still made up on this last plan we have another plan that we like better. At the commencement of the honey-flow the division is made and the cell is given in *four* days, and the brood set off on its own stand on the *eighth* day after the division. At this time the brood is all capped so that there is no loss there. While this method takes three days more of hatching bees away from the colony that is left on the old stand, which is our honey-gatherer, we make *two* colonies from the brood by dividing it in the middle, giving each half an equal part of the bees, brood, and combs of honey. Each half is also given a ripe queen-cell; and although one of them will have the virgin and will, therefore, destroy the cell, it saves work in the end and is the better way. By making these nuclei of the divided brood early, they breed up rapidly and make just as good colonies for winter as if the brood had not been divided. There is this difference, however; that is, brood not divided in halves in the way I described might have enough stores for winter, while the two halves of the divided brood would have to be fed some syrup to carry them over to the next season.

While this latter plan costs only half as much honey in the first place as does the plan first described under the heading, "The Alexander Plan of Making Increases," yet more sugar has to be fed for winter stores, but not enough more to offset what is gain-

ed, and it is, therefore, a very good plan. It will be noticed that, in the plan of making two nuclei from the brood of one colony, only half as many colonies need to be disturbed to make up the winter loss, and in those which are disturbed to make up such loss, the colonies left on the old stand containing the working force are in about the same condition after the brood is removed, as to the amount of honey that would be stored, as a new swarm would be if hived on the old stand.

#### THE ALEXANDER PLAN AS WORKED FOR INCREASE.

In making up winter losses I have advised the use of drawn combs. In making increase, frames of wired foundation are used instead. Sometimes it happens that we have both increase and winter loss to make in the same yard, and in such a case a frame of brood containing the queen is placed in a hive containing frames of foundation. A queen-excluder is placed on top of this, and then the brood over the excluder, so that all is on the old stand just as usual. On the eighth day the brood is set off on a new location, and is used to make up the winter loss as I have explained.

The difference lies in the fact that no story of extracting-combs is given the colony until the foundation has all been drawn out and filled with honey and brood; for, were we to give all the comb room the bees would use above, the foundation would be neglected, and probably there would be no colony at all, so to speak, for the bees might not have more than two frames of the foundation drawn out, nearly the whole force of workers being above. In order to avoid having seven-tenths of the hive below untouched, therefore, see that this foundation is all drawn out before stories of extracting frames are given.

In the above discussion I have purposely said nothing about a flow of buckwheat honey, having taken into consideration only the white-honey flow of June and the fore part of July. Here at Remus we get some dark honey from the buckwheat and aster. Some of our winter losses in years past have been made up during this flow. While it is somewhat cheaper than to do it during the white flow, I am very sure that such colonies are not worth as much as those made earlier, judging from what the bees are able to accomplish in storing surplus the season following; and it seems that these little swarms are a little on the order of late natural swarms, for they do not winter as well, and they are, consequently, not as desirable. We have, therefore, come to the conclusion that, while it costs more to make our increase early, it is cheaper in the end, and therefore we try to do that at the present time.

A practical honey-producer can buy bees of less successful bee-keepers for much less money than he can produce them himself, if he can find any for sale that are in a desirable condition. Sometimes we find desir-

able bees, and in such cases we buy them instead of trying to make our own increase.

#### THE CHAPMAN PLAN OF MAKING INCREASE.

Mr. S. D. Chapman has a plan somewhat different from these others mentioned. At a period about eight days before the close of the raspberry flow (it would be the same if the flow were from clover or basswood), he hunts out and kills all his queens with the idea of having only young queens with which to go into winter quarters. In ten days, when the queen-cells that have been started come to maturity, half of the bees and brood, including a good queen-cell, is taken out of as many colonies as desired, and put into empty hives, and then both hives are supplied with empty combs from the colonies that died during the winter. As this is about the middle of July, these half-colonies that will soon contain young queens will build up into good colonies for winter, although they will probably need to be fed quite a quantity for winter stores. The bees have eight days of the last of the honey-flow in which to build their cells, which insures the best quality of cells. Furthermore, at this time it is less expensive in the amount of honey it takes to produce the increase; for when one runs for extracted honey, as Mr. Chapman does, this killing of the queens is not likely to cause any loss of honey; and the smaller amount of brood the bees have to care for may be a gain rather than a loss. Finally, by having young queens take their flight after the season is over, there is less than one per cent of swarms during that time. We have tried this plan and found it to be a good one.

Mr. E. E. Coveyou, of Petoskey, usually has his own way of doing things, and his method of making up winter loss and working for increase is no exception. When he finds cells being built in any of his colonies preparatory to swarming, the colony is shaken into a hive filled with combs or foundation.\* After the bees and queen have been shaken from the combs, the brood is removed to some weak or moderately strong colony, to be taken care of for six or seven days. At the end of this time the brood is placed on a bottom-board beside the before-mentioned medium colony, over which it has been for the previous few days, and both hives are so placed as to get about the same number of flying bees. A new colony will thus be made from the brood.

If he desires to make two colonies from the brood he divides it and sets the two halves on the old stand so as to catch all of the flying force, the original medium colony of this stand then being moved to some other stand. If there are cells to be saved in the brood, a queen-excluder must be used between the upper story of brood and the medium colony before the division.

If this brood from the shaken swarm had been set on a stand of its own at the time of shaking, much of the unsealed larvæ would

\* If one has the foundation, this is the place to use it, for the combs may be used later.

have been lost by the bees leaving it and going back to the old stand.

If Mr. Coveyou finds that more increase is needed than he can get from the colonies having cells, the required number of cells are provided by the plan already described.

Remus, Mich.

## BEE-KEEPING IN NEW MEXICO.

### Some Problems not Ordinarily Met.

BY THE NEW MEXICO CHAP.

Couldn't Mr. Alexander and others, in giving dates, refer to an expected honey-flow, to the time when bees first begin to get nectar, to a killing frost, or to some such terms, instead of May 1, etc.? I am down here in New Mexico where the bees fly every day in the year. To-day, Dec. 28, I saw a great number of them follow a load of honey two and a half miles, and swarm around the wagon for a long time after it was unloaded. I have just been reading GLEANINGS for Dec. 15, p. 1594, where Mr. Alexander is quoted as having said he began extracting from the brood-nest May 1. Reference to a certain day of the month, or even to a certain month in your locality, means little in the way of actual information to me. Not having the conditions of climate, season, and flora tabulated in my head for the whole United States the phrase "May 1" for Ohio leaves me to guess *when* I should do the same thing in case I wish to try the plan. I believe Mr. Alexander did in the original article specify so many days before the first flow; but if such explanations were more generally used they would help me. Could you not, in some place in your columns, explain this point to the kind writers of GLEANINGS, and thus help your readers of the Southwest?

Many of the articles I read leave the impression that the writer had never conceived of such conditions in the bee business as confront me. For instance, I wonder if "Crudh" would be thinking and writing the same as he did for Dec. 15, pages 1592 and '93, if he were here, where English-speaking help is hard to get, working to put 1500 run-down colonies, scattered over ten square miles (one yard even 45 miles away), in shape to breed up to 2500 next spring, and to produce a given number of pounds each, in order to meet interest and principal where you must have gilt-edged security to get money at 10 per cent. I wonder if he would figure long whether or not a queen was too black to keep, or whether she was one or three years old. Perhaps his mind would be on where he was going to establish those new yards; how he was to get the wells put down, whether he would have to have a horse here, etc.

If the gentleman who opposes Dr. Miller's idea of controlling bee-ranges had to "buck" this sort of proposition from twelve to eighteen hours per day, I wonder if he would call it pastime, or if he would get some stronger words for it.

Now about taking off honey in the after-

noon so the bees will not sting you and the neighbors. What about taking it off from daylight until dark, and working at the extractor away into the night with the bees lying idle for weeks at a time for want of empty combs where help can not be had?

I should like to hear more about "going Mr. Alexander one better" by taking out combs and letting bees carry the honey back to empty ones in the hive. We have several thousand pounds of honey candied in the combs, so white and dry that all the power extractors in the United States would not throw it. Suggestions thankfully received.

Mesilla Park, N. M.

## INJURY TO LEAVES OF BASSWOOD-TREES.

BY PROF. H. A. SURFACE.

Can you tell me what to do with my basswood-trees? Every year something eats the leaves full of holes. I fear it hurts the bloom and prevents secretion of honey. I have 25 trees, one foot in diameter. They bloom full some years, and the bees work on them ten days or two weeks, some years two days. What causes the injury is so small that it is impossible to see it. Sometimes I see a very small worm. They make a perfect sieve of the leaves. J. V. N. HOUSE.

Spring Hill, Kan.

[This was referred to Prof. H. A. Surface, Economic Zoologist at Harrisburg, Pa., who replies:]

It is evident that the injury to the leaves of the basswood-tree described in the above inquiry is due to beetles, which are, no doubt, either rose-bugs or June beetles. The latter are sometimes called May beetles and drone beetles. The work of making the leaves full of holes is indicative of these creatures. Worms or larvæ may eat holes in the leaves when they are very young, but they soon go to the edge and eat away the tissue from the margin of the leaf. Also if the work were done by worms or larvæ these pests would be present in great numbers and quite conspicuous. The beetles feed after night, and the June bugs or May beetles may disappear entirely in the daytime, finding concealment in the grass and soil. If the damage be done by beetles, remedies will be difficult to apply, for the reason that these pests are so slow to poison that it is generally considered impossible to kill them by poisons. The best material to apply as a spray would be arsenate of lead, two pounds dissolved in fifty gallons of water. This would stick better than any other poison that could be used. It will not be washed off readily by rains, and will be present when needed. It should be applied upon the first appearance of such injury. If the damage be done by worms or larvæ this would undoubtedly be the best remedy to use, and spraying with Paris green would be next in order.

Sometimes it is possible to catch the leaf-eating beetles on cloths soaked with kerosene

by tacking such cloths to a frame stretcher and shaking or jarring the branches over them after night or in the early morning when the insects are yet present. If the beetles merely fall into the kerosene-soaked cloth they will eventually be killed through contact with the oil, even though they may be able to escape temporarily.

To overcome the effects of such injury it would be well to saturate the ground by the application of a little nitrate of soda, a mulching of stable cleanings, or some other nitrogen-bearing material applied around the tree as far as the branches extend. Cultivation of the soil to preserve moisture is advisable, but this can not always be done. Abundant watering will help the trees greatly in overcoming the effects of such injury.

It is difficult to name insects with certainty without very accurate descriptions of both the pest and the injury that is inflicted or without the insects themselves. It would be advisable for inquirers to mail us specimens, and thus be accurately informed instead of being obliged to rely upon assumptions from descriptions that may not be complete.

#### SOME ALFALFA HONEY THAT COULD NOT BE LIQUEFIED BY HOT AIR.

In regard to liquefying honey, p. 145, Feb. 1, I will say that last November I had to warm up about 150 ten-frame supers to extract them. For this purpose I built an 8×12 room and used a small coal-heating stove, and maintained a temperature from 110 to 130° for 24 hours, and had alfalfa honey in the room for three days in 60-lb. cans, and it did not liquefy in that length of time. I also had some honey in supers that was candied, and it is still in the frames. In addition I had a 6000-lb. storage-tank that I tried to get the sun to warm up last summer when it was ranging 100° in the shade, and it was a failure. I have had to shovel out 18,000 lbs. of honey in the last year, and scorched only seven cans, and they were one-gallon in size. I think that, to use hot air, would be expensive—that is, to accomplish the purpose. Of course, some kinds of hot air are very cheap.

M. TOWNSEND.

Ontario, Ore.

[Our experiments in liquefying candied honey in an incubator lead us to believe it would take nearly a week with a temperature of from 110 to 130, to liquefy honey granulated so hard that it is solid.

The combs containing the honey in such a temperature, in a few days more would have

sagged or crushed as soon as the honey had begun to melt.

In the case of a large 6000-lb. tank of honey which was candied, the sun would never affect it. The same thing has been tried in California, with a much warmer climate, without results. The only thing to do in a case of this kind is to do as you did—shovel it out and melt it over hot water.—ED.]

#### SHIPPING HIVES IN BOXES.

The whole bee-keeping fraternity should insist on manufacturers shipping hives that are sent out in the flat in closed boxes instead of using the hive-bodies for the crate. I presume this is done to reduce the freight charges to the lowest possible point; but I believe the majority of bee-keepers would be willing to pay a little more freight and have their supplies arrive in as good a condition as when they left the factory. I am of the opinion that, if the shippers of hives packed thus could be at the destination point and see them unloaded they would very often feel like disowning them.

In unpacking the shipment the contrast is so great that one can scarcely realize the shipment is from the same factory. The inside hives are as bright and clean as a new pin, while the hives set up as the shipping-crate are black and greasy, contain several nail-holes, and the soft pine wood is marred, and the body dented and often cracked by rough freight-handlers *en route*. The hives are always shipped with the hand-holes on the outside of the package, probably to afford a place for freight-handlers to handle them, and of course they must be put together this way. In a shipment of even five hives, two sets of hive-bodies put together are necessary to hold the rest of the hive-fixtures. We see by this what a large amount of extra work is necessary to put such hives in proper shape. Not every bee-keeper has the tools or the time to plane, dress, trim, and putty the nail-holes of these marred hive-bodies, nor should they be expected to do so when they pay for doing this very thing at the factory. GRANT STANLEY.

Nisbet, Pa.

#### QUEEN WITH DENT IN HER BACK.

In June, 1907, I purchased a breeding-queen and introduced her into a hive with two frames of brood taken from another colony. During the month I added two more frames of brood, and the rest of the hive full foundation—Danzenbaker hive—until now the colony is very strong in bees, thousands hatching every day. When the queen arrived, there appeared a small dent on the back between the wing-sockets, perhaps as large as a pinhead, and  $\frac{1}{30}$  of an inch deep. The cause of this dent does not seem to be very clear, nor does it affect her laying qualities or her offspring in the least.

To-day I opened the hive to show the queen to a visitor, and the first frame lifted out contained a beautiful large queen, and upon close examination the dent was not vis-

ible. While we were looking at and admiring her my attention was attracted to another part of the frame, when, lo! there was the old original queen on the same frame and same side of the comb, but the newly discovered queen was the larger by all odds. I then looked through the hive for queen-cells, and found *one* hatched out. Do you think the bees are trying to supersede the other queen, or what?

Granby, Conn.

E. H. SHATTUCK.

[In these cases it is evident the bees had in view the supersedure of the old queen. The dent in her body probably incapacitated her to an appreciable extent, and hence the presence of a new and vigorous queen. — ED.]

#### A SUCCESSFUL PLAN FOR WINTERING TWO QUEENS IN A HIVE.

In reference to the two-queen system of managing bees, I will say that I divide the hives with a thin division-board, bee-tight, from top to bottom. Two nuclei will then winter just as well as a full colony in either an eight or ten frame hive. In this way we have the two queens in the spring; and if a queen is needed for another colony, one queen can be removed and the division-board taken out. I am enthusiastic in recommending a divided hive for wintering bees. I take two colonies and put them in two divided bodies, one on top of the other, so that each colony occupies half of both bodies. In this way the heat of both colonies is in one hive.

It always has been next to impossible for me to get my colonies built up in time for the white-clover honey-flow. Now when the flow begins I put the two colonies, each with its queen, in two undivided bodies, both of which are on the same bottom-board. Two section-supers and an excluder are between

the two colonies. Besides the regular entrance there is an entrance above the supers, as shown in the diagram. The bees keep right on rearing brood; and when they get too numerous for two hives and three or four supers I remove the top colony to another stand.

I recommend this system only for wintering and for building up in time for the honey-flow. Last winter was the first time I tried it.

B. D. HALL.

Royal, Ill.

#### NAILS KEPT IN CIGAR-BOXES.

I think I have quite an improvement over Dr. Miller's nail-box as illustrated and described in the Dec. 15th issue. I use ordinary cigar-boxes, nailing the lids securely at one end and half way up the sides, using regular cigar-box nails. Then with a sharp thin-bladed saw I make a cross-cut through the middle of the lid. I then have practically the same box as Dr. Miller's, with added advantages of a lid, keeping out dust, etc.; less trouble to make, and no cost whatever, as the boxes can be secured for nothing at almost any cigar-store, grocery, or drug-store. If it is desirable to hang it up, as Dr. Miller suggests, it is only necessary to tack a small strip along the bottom, leaving a projection with a nail-hole at the top. However, I find them more convenient to lay the box flat on a shelf with a nail, like contents, fastened on the end of the box for a label.

Piqua, Ohio. M. E. McMANES, M. D.

#### TOP AND BOTTOM STARTERS FOUND SATISFACTORY IN CALIFORNIA.

I have just read the article by W. A. Pryal, p. 1582, in which it is stated that top and bottom starters in sections did not work satisfactorily in his locality. Now, I live in Alameda Co., not over twenty miles from Oakland as the crow flies. I use top and bottom starters according to Dr. Miller's directions, and the results are all right. I do not think locality has any thing to do with his trouble. I think the trouble is with his bees; but I am only an amateur in the business, and write this to let you know that all Alameda Co. bees do not fill their sections in a freakish manner.

S. C. GIBSON.

Niles, Cal.

#### SCREENED ENTRANCES TO HIVES IN A CELLAR NOT SATISFACTORY; WHY ONE COLONY HAD DYSENTERY.

I screened the entrances of the hives the first four weeks after I placed them in the cellar; and if I had left them closed I should not have had a live bee to-day. With me a closed entrance is a failure.

I placed my bees in the cellar Nov. 15, all in very good condition, with plenty of natural stores. The first two weeks in the cellar they were very quiet; after that they began to be uneasy, and finally to roar, and the thermometer began to rise, and went up to 60, with a strong smell of dysentery, which I traced to one colony. (The date of my examination was the first week in December.)

That one colony had dysentery in a very bad form. I removed it. I placed ice in the cellar, opened up my ventilators, opened up the entrance, and cooled down the cellar to 40; shut up the cellar, and up to date my thermometer stood at 48 at every examination, with all ventilators open. Now, why was one colony affected and not the rest? It was a colony that swarmed on the 23d of August, and the swarm was put with a weak colony that was queenless.

Estey, Mich.

MILO WRIGHT.

[We are unable to answer the question without more particulars.—ED.]

#### CATCHING STRAY SWARMS.

To trap stray swarms, I secure a number of boxes at the local stores, of different sizes. The covers are cleated, and fastened on with four large screw-eyes to avoid the bother of a screwdriver. In one side of the box is a hole which is covered with a wire-cloth door. Finally, a screw-eye is put into the top back edge of the box with which to hang it up.

With a ladder I go up a tree, drive a nail, hang the box, see that the door is open, shove in some comb honey, and go away. Last spring I caught five swarms in four boxes; and had the season not been so late (after June 10th) I should have captured many more. As it was, I got 14 swarms, from which I put away nine with honey enough in the hives to keep them over winter.

The bee-trees have been pretty well cut out of the little grove adjacent to my home; and as the bees come to the grove, seeing the trees from afar, it is only natural that they should go into a nice, clean, inviting hive.

DR. A. F. BONNEY.

#### EVAPORATING HONEY IN A VACUUM-PAN AT A TEMPERATURE OF 120 TO 140°.

I have read several articles in GLEANINGS on the evaporation of honey; and as I am a practical sugar-boiler I thought perhaps my experience and ideas might reveal something new in the way of evaporating or candying honey.

Honey can be boiled or evaporated in a vacuum-pan at from 120 to 140° F., and I think without injury to the same, excepting that it may granulate. Cane syrup boiled under a vacuum will granulate in a few days; though whether it would have the same effect on honey I can not say; but even so, if we could evaporate honey and retain its color and flavor, converting it into sugar or candied honey in a few days, I think it would be a paying proposition.

There is a small vacuum-pan at the Louisiana experimental station, New Orleans, where an experiment could be made at very little cost.

W. H. RAGAN.

Siloam Springs, Ark.

#### PETROLEUM TO PREVENT ROBBERING.

I am in the petroleum regions of Kansas, and when there is any robbing going on in my apiary I simply soak some old gunny sacks in the crude oil and wring them out so

no oil will drip, and place them over the hive that is being robbed except the front. Then I close the opening to a small space. The robber bees generally want to try every spot about the hive before they make an attempt to go in at the regular entrance.

Chanute, Kan.

JAMES FRAZIER.

#### TOP AND BOTTOM STARTERS VERY SATISFACTORY.

Last year, 1907, I put starters in 10,000 sections with the top starter from 1½ to 2 in. deep, and bottom starter from ½ to ⅝ inches. During the two previous years I used probably 20,000 sections with top starter from 1½ inches to half full. I never had a single case of malformation, every section being straight and evenly filled, with no discrepancy in the cells that I noticed. Two sections that I remember as being left over from previous year had a line of wax at bottom, but with a little projection in the center of about ¼ inch. I put a starter at the top and left the bottom as it was. The finished sections showed a tongue-like formation in the middle, showing that the bees had built up from the little projection of foundation at the bottom. These were the only two bad sections, and even they were straight, as I use separators. I think the same plan of using starters is used all over Colorado.

R. S. BECKTELL.

Grand Valley, Colorado.

#### THE REASON FOR THE LOW PRICES.

I notice the honey in our stores is just as the bees left it. When inquiring as to the price paid for such honey I find that it is usually about five or six cents below the market price; yet the producer can't afford the subscription price of a bee-journal and learn to clean, grade, and market their section honey. I have a fight here every fall to get a honey market, as these fellows will bring in a super or two (if they have that much), and seem to be afraid of overstocking the market, and are glad to sell their stuff at any price. Of course, our merchants get it cheap, and that establishes the price. The happy-go-lucky farmer has sold his honey, and goes home to return and do the same thing the next fall.

J. W. URSH.

Belleville, Mich.

[Better buy him out or get him to put their honey up in good shape and maintain prices with you. It is to *his* interest to do so.—ED.]

#### THE RICH-ALEXANDER PLAN OF PREVENTING SWARMING.

I wish to say a word in regard to the Rich-Alexander plan of non-swarming as given on page 644, May 1, 1907. A year ago I had four colonies equally strong, and I manipulated two of them in accordance with this plan, with the result that I have taken honey from them but no swarms. The other two swarmed—no honey yet, and increased to five colonies. The Rich-Alexander plan for me, after this.

New York, N. Y.

# A CHICKEN THAT LEARNED TO CATCH DRONES BUT NOT WORKERS.

After reading Mr. Franklin G. Fox's article in regard to feeding drones to young chickens, on page 1505 of the Dec. 1st issue, 1907, I felt that I should like to give my experience. Last summer my bees were located near my poultry-house, and the chickens used to run in my bee-yard a great deal. I had one chicken that had learned to kill bees and eat them. It seemed strange to me that it never seemed to get stung. It would walk up to a hive, catch a bee, walk off and beat him on the ground, and then swallow it. After this, it would repeat the performance. It seemed to have certain hives it worked on, and these were pure golden Italians.

I killed the chicken and began to dissect it. I examined his crop very closely, and found it contained 27 drones and not a single worker. This astonished me, because I had expected to find a lot of workers instead of drones.

If I had only known that the chicken was destroying drones only, I would not have sold it at any price. The chicken, I suppose, knew the drones by their size and shape.

E. S. HUDSON.

## QUEBEC BEE-KEEPERS' ASSOCIATION.

On February 5, in the City Hall of St. Hyacinthe, there was a meeting of a considerable number of bee-keepers of the province of Quebec, for the purpose of forming a bee-keepers' association. The chair was occupied by Mr. C. Péloquin, M. C. A., of St. Hyacinthe, as president of the meeting, and A. O. Comiré, M. D., as secretary.

In a few words Mr. Péloquin explained the purpose of the meeting, and upon his proposition the following resolutions were adopted:

That an association known as the Quebec Bee-keepers' Association shall be formed in the province of Quebec, and shall be composed of those interested in bee-keeping, who become enrolled as members by paying the annual membership fee of one dollar to the secretary of the association.

That the direction of the association shall be composed of nine members.

That the following persons shall be the directors:

Chas. Péloquin, of St. Hyacinthe; Hector Béland, of Louisville; Théodule Cloutier, of L'Islet; Napoléon Gaudet, of St. Simon; F. W. Jones, of Bedford; J. A. Camirand, of Sherbrooke; Dr. J. L. Comiré, of Yamaska; Michel Dufault, of St. Joseph of Sorel; Onésiphore Fontaine, of St. Guillaume.

That the president shall be Mr. C. Péloquin, of St. Hyacinthe, and the secretary A. O. Comiré, M. D., of St. Francois du Lac.

That the Hon. Jules Allard, Minister of Agriculture, shall be asked to bring before the government, at the next session, a law providing for the legal formation of bee-keepers' associations in the province of Quebec, and another law providing for the suppression of foul brood among bees.

SECRETARY.

# IS IT ADVISABLE TO MAKE A COLONY QUEENLESS 24 OR 48 HOURS PRIOR TO THE INTRODUCTION OF A NEW QUEEN?

How long would you advise me to take the old queen away before introducing the new one?

C. W. BARR.

Florence, Kansas.

[It is our rule to take out the old queen, and cage the new one to be introduced, at the same operation. There is nothing gained in waiting 24 or 48 hours, according to our experience. If a longer time elapses, the problem of introducing is considerably complicated, for the reason that the bees get into the notion of raising their own queen, start building cells, and when these are once started they are inclined to act unkindly toward the new mother to be introduced.]

It very often happens that a customer will remove a queen from his hive and then send on to a queen-breeder asking to have a queen sent by return mail, which he intends to introduce to the hive just made queenless. Perhaps the queen-breeder is unable to fill the order promptly. A delay ensues, during which cells are started, and by the time the new queen-mother arrives she is quite likely to be maltreated, if not killed outright.

Never remove a queen from a hive until you are sure that you will have another at least within 24 hours. There is no objection to keeping the hive queenless for that length of time prior to the introduction of a new one; but such queenlessness should not continue for a longer period.—ED.]

Balance in my favor.....\$131.75

\$131 75

In this account I have not counted what I gave away and what we used up to Dec. 1, and we have used no little amount, for there are eight of us.

Underwood, Ind. RALEIGH THOMPSON.

## A CORRECTION.

The directions for making the spacing-blocks, in my article on page 432, April 1, should read, "A fraction less in thickness than *half the width of the section.*"

Meridian, Ida., April 14. G. J. YODER.

## OUR HOMES

by A. I. ROOT

Trust in the Lord, and do good; so shalt thou dwell in the land, and verily thou shalt be fed.—PSALM 37:3.

Quite a few periodicals are sent me on socialism; and, to tell the truth, I am flooded with periodicals devoted to almost every *ism* under the sun, it would seem, and therefore it is impossible for me to do more than to glance over them. Perhaps I should say that, as I grow older, I find it beyond my strength to read books and papers as I used to do. For some years I have felt it a sort of duty to look over at least *one* daily paper.

I do not want to miss the good things that are coming so constantly in regard to the victories of the Lord Jesus Christ over the sin of intemperance; but I have just been thinking that I shall have to give up reading even the daily—at least as much as I have been doing. Not only my health, but my very life depends on being out in the open air many hours of the day. I make this suggestion to you, dear friends, because I want you to know that I can not read books and periodicals as I used to do. Now, with all this prelude I want to say that, in glancing over the periodical called *The Study of Socialism*, my eye caught the following sentence:

"Whenever one man gets a dollar that he has not earned, it is a sure thing that some other man has earned a dollar that he did not get."

I want to say *amen* to that statement, and make an application of it in regard to this matter of selling secrets, or, if you choose, selling a much advertised book for five or ten times what it is actually worth. Perhaps I might say a hundred times. And this whole business of taking a dollar, more or less, for some information that can be printed on a small piece of paper, is robbing somebody, probably, of a hard-earned dollar. Our text tells us to trust in the Lord, and do good; but a man is *not* trusting the Lord nor *doing* good when he takes money for "secrets," especially the sort of secrets where one signs a contract not to let his neighbor have the secret nor let him see the book.

There is another way of getting money that really *does* do your neighbor good; and that other way is what I am going to talk about to day. Yes, I am going to have another chicken story. While in Elmira, N. Y., last week I called on a bee-keeper of years gone by. He was very glad to see me, and before I left he introduced me to his wife, who is a bright and interesting woman. Her eyes twinkled when she heard my name, and it was a pleasure to see me. Then she added that she wanted to find a little fault with my last Home paper. I began to be trou-

bled right away; but when she explained that her only objection was that it had *nothing* in it about chickens, I felt better. However, her good husband (Mr. P. F. Conklin, who is a railroad engineer), so strongly indorsed my temperance talk that I felt as if I had not gone very far amiss, take it all together, after all. And, by the way, there are so many of the women-folks who have been asking for more "chicken stories" that I do not know but I am warranted in taking a little space for that subject—a subject dear to my heart, even if this is a bee journal.

I want to say something more about my visit to friend Philo's in Elmira. His only son is named Ernest—E. R. Philo; and although the father has been a "chicken crank" all the days of his life, as well as a bee-keeper, his son did not seem to take much of a shine to either bees or chickens. His great craze from boyhood up was printing. In fact, while quite a boy he got a little printing-press, like the one I started with, perhaps, before we published GLEANINGS. Well, this boy could think of nothing, day or night, but nice clean printing; so after his father got to doing so much with chickens that he needed some sort of communication with the great outside world, his boy started a poultry-paper. But for some years, owing, probably, to the great number of other poultry journals (somebody has told me there are close on to one hundred of them in the United States), they did not succeed in working up a very large subscription list. I think that, about a year ago, 1500 subscribers was pretty nearly the sum total. The boy is now just about 21, bright and wideawake, with a pretty good physical frame for hard work. Well, that list of 1500 names has, during the last year, run up to over 12,000. I do not know how it came about—probably largely on account of the father's development of new things for poultrymen during the past year.

While talking with friend Philo about his "fireless" brooder I asked him several questions about the traffic in baby chickens one day old. Later I noticed an advertisement in the poultry journals of several establishments near my own home that do nothing but ship chickens as soon as they are hatched. I sent for their circulars, and yesterday, April 14, paid a visit to three of them. The first one I called on was owned by Jos. A. Bloom & Co., Chatfield, O., and I was delighted to find the whole establishment under the care of a young man not much older in appearance than Ernest Philo—may be 25 years old. A new building has been put up since January, and this building contains 48 incubators of 200-egg capacity each, all in full blast, and he and his younger brother were very busy in making *more* incubators. Instead of paying a big price to the incubator factories they just make their own, and they claim that these home-made ones will do as good or better work than any they can buy. Just think of it! A couple of *boys* practically making incubators that actually give splendid results! As a matter of course, they have sent for samples of almost every

thing advertised to help along the poultry business. But a great part of them are practically of no account. For instance, I noticed a \$2.00 egg-tester that I had been thinking of sending for. Mr. Bloom said he did not find it a bit better for *his use* than the common 25-cent ones. Of course, there is a great deal in getting used to a new machine or apparatus.

The next call I made was at the Old Honesty hatchery, of New Washington, O. They have a room similar to the one just mentioned, containing 82 incubators of 200 eggs each. These incubator rooms or cellars are partly under ground in order to secure a uniform temperature. The upper story is used as a workshop. I wish to congratulate these men in both places on having their rooms, incubators, and every thing else kept so neat, clean, and businesslike. The arrangement I had made to meet a special train was of such a nature that I did not have as much time as I really wished in order to look over the different establishments.

My third and last call was at M. Uhl & Co.'s, New Washington, O. These folks have been in the business for about eight years. Last season they sold 82,000 chickens, but did not succeed even then in filling orders. Their shipping-day is Tuesday, and I suppose their incubators are started so as to have chickens come out, say on Monday. On Tuesday the chicks would be dried off enough to put into little pasteboard boxes holding not less than 25, which can be sent by express even in cold weather. As small number as ten can be sent safely after May 1. Twenty-five chickens in a box weigh only 4 lbs. You see they are lighter than eggs. I presume some arrangement is made with the express companies so there shall be no delay. The day I was there, Tuesday, they had sent out about 6000 chickens. I had a box of 25 of different kinds that I brought home to experiment with in my home-made "fireless" brooder. The prices run from 7 to 15 cents. The Leghorns are usually the cheapest. They also make a special low rate on all the "odds and ends" that are left. I supposed at first that they had poultry-yards of sufficient capacity to produce their own eggs for hatching; but I learned that this was next to impossible. They get their eggs from farmers and others in their vicinity who produce them for this particular purpose, the proprietors of the hatchery probably furnishing the stock. I judge this to be so, because they have some very choice high-priced stock. All the parties engaged in the business told me that they had very few losses. The packing of chickens is opened in the presence of the express agent, and he certifies to the number of dead, if any. The shipper then replaces these with another shipment or makes some satisfactory arrangement, if the number lost is small. A shipment made from New Washington, O., to Tampa, Florida, occupying four days, was received in very good order, and the chicks did not seem to be much the worse for having lived four days without food or water. In fact, I believe the general

decision is now that chicks are better off without any thing to eat for at least 48 hours after they break the shell. Of course, it is important that the purchaser be on hand at the express office to take charge of the chicks just as soon as they are received.

I said in the outset that there is another way of getting money that does your neighbor good. These two boys, with their honest enthusiasm, one for printing and the other for raising chickens, have no idea in their heads of any thing else than earning their money in a way that *will* benefit their neighbors and bless mankind. They may not be exactly trusting in the Lord. I did not see them long enough to find out about that; but I rather think they are; and their hard honest work, especially the particular work of striving to please their customers, is a sort of Christianity that even some church-members do not possess. The chicken boy and the printer boy both have to satisfy their customers in order to prosper. These boys and these people I have described are doing good. We see that by the letters they give in their catalogs. And they are going to be fed, and clothed too; and every boy and man who is doing an honest day's work every day of his life is a credit not only to his country but to the great Father as well. You may be quite sure that these boys have no bad habits. They are so busy they do not have any desire, even if they had the time.

Now, friends, this new rural industry is not only interesting to me because I have made a study of chickens, especially of late, but because it illustrates how things are changing, and what wonderful strides are being made in almost every thing used on the farm as well as in the great cities. T. B. Terry was one of the first to exhort farmers to choose some special line of farming. He decided to be a potato-grower, and bend all his energies to the task of growing more potatoes, and better ones, than had previously been seen. Thousands and thousands have had success far beyond what the farmer did who tried to grow every thing usually secured by a farmer. Bee-keepers will remember when almost every farmer had a few hives; but nowadays the bee-men mostly have large apiaries and make it their sole business. But even the bee-keepers, like poultrymen, are dividing up into specialists. The man who makes the production of honey his special line does not often have queens to offer for sale. The queen-breeder makes it *his* special business. One man produces extracted honey, and another one produces comb honey; and, if I remember correctly, the number of those who work for both comb and extracted honey is growing less every year. There has been talk about having bee-keepers, in localities where it would be expensive to ship honey, make a business of producing *beeswax* and nothing else. I do not know that this has, as yet, been realized. In the poultry business we have egg-farmers where they raise eggs for the table, and nothing else. Then we have broiler-farms; but I am told that these two do not go very well together.

They need a different strain of fowls for broilers (or capons) from those for eggs only. In these large establishments they grow special breeds for special purposes, where they have single male fowls worth a thousand dollars or more—that is, they *claim* they are worth that, but it looks to me, however, as if these very high-priced fowls come pretty near the line of what the socialist paper said about the man who got a dollar that he had not earned.

Last, but not least, it looks as if somebody who is an expert, and has his heart and soul in the business, is in the future *going to hatch the chickens*. For instance, a busy man or woman can not very well afford to fuss with a single incubator. If they do it for fun or pastime, all well and good; but when one is in the business he can almost as well run a dozen incubators placed in a proper cellar as to have just one. I thought at one time that sitting hens might be safer and simpler than incubators; but during the last two or three attempts at setting my hens, they broke so many eggs, especially where I undertook to give them twenty or more, that I began to think I preferred the incubator. Another thing, one of my hens made a very good hatch out in the woods down in Florida, in a grassy thicket, where you could hardly crawl through. I could catch the sitting hen; but the chicks hid in the grass and bothered me so much that I almost concluded I did not want to set another hen.

They claim they can furnish hatched chickens at just about double the price you would have to pay for eggs of the same kind; and I judge there is but very little difficulty in raising the chickens by our best modern methods after they are once hatched. If this were not so, the customers of former years would not be patronizing these same establishments year after year.

Now, what lessons are we to learn in regard to this new development and the new condition of things that is coming up all around us? Some of us older people often get into a way of speaking about the "good old times when we were young." Yes, we may get the idea into our heads that the world is going to be "civilized out of existence," as I have mentioned, unless something is done about it. But I think that, when we come to look the situation fairly in the face, we shall recognize the hand of a loving Father in it all. Please say to yourself when you are tempted to complain at modern innovations, "Lord, help us to learn the lesson thou art striving to teach us;" and then go on smilingly, trying to see the good side and overlook the objectionable features of the new ways of doing things that are coming up all around us. And let us finally decide, in the language of our text, to "trust in the Lord, and do good;" and have faith to believe that we *shall* be "fed" and clothed.

#### DAY-OLD CHICKS, AND "FIRELESS" BROODERS.

At friend Uhl's I saw a very bright young woman handling the chicks and otherwise

helping in the incubator-room; and it occurred to me that this is emphatically a woman's work. Who can handle chicks, especially "baby" chicks, to better advantage than women or girls? And, by the way, that I may know how fast this new industry is spreading I wish all those who make it a business, who are taking GLEANINGS, would give me their names on a card. I believe it is an industry that should be encouraged. I will give the names of all free of charge. Just one thing more: Will all those who have tested the fireless or lampless brooder please give me a postal-card report as to how far they have succeeded? I have had 25 chicks two days in the home-made "fireless;" but last night, when there was a rather heavy freeze and a strong north wind, I put them in the house over night. Perhaps I did not need to; but I had not quite courage enough to leave them *entirely* without any aid from artificial heat.

#### CELERY CULTURE IN MANATEE CO., FLORIDA.

On pages 556 and 557 I give you some halftones showing Mr. Lattimer's five-acre celery-farm described in our last issue. On p. 160 of GLEANINGS for Feb. 1 I also gave a brief account of Mr. A. F. Wyman's irrigation with the overhead sprinkler system. Mr. Wyman also includes celery in his plant of 35 acres. It was my good fortune to meet both of these progressive men at Bradentown a few days ago. While congratulating them on the success of their respective celery-farms I suggested that Mr. Lattimer's two big artesian wells accomplished the irrigation at probably less expense than Mr. Wyman's expensive sprinkling outfit. The latter gentleman, however, took me up at once and said, "No, no, Mr. Root, you have got it entirely wrong. It does not cost me nearly as much to irrigate my celery with the appliance I now have as it does friend Lattimer, and I think Mr. L. will agree with me."

When I visited the Lattimer plant I told you the water looked as if it was almost knee-deep in some furrows between the plants; and with furrow irrigation I am told it is often necessary to give the celery too much

\* My good friend Uhl is a very pleasant sort of man, and some of the expressions in his catalog are quite refreshing. For instance, in his directions how to handle chicks after you get them at the express office he says:

As soon as you receive the chicks put them in a warm place, in a good brooder or with hens. Do not let them stand around and holler. It is very important to feed only a little at first, as they are likely to eat or drink too much.

After I got my chicks home, and they got a little too cold, I could well appreciate his warning, "Do not let them stand around and holler."

water in some places in order to get the water to the spots that have not enough. Perhaps a careful grading and a right slope of land would remedy this somewhat. With the overhead sprinkling, however, the water can be put just where it is needed, and nowhere else; and, if I am correct, the amount of water required is much less than where it comes in the furrows. Where the soil is very porous, as it is almost all over Florida, quite a large portion of the water in the furrows will go down below the wants of the plants; whereas with the overhead sprinkling, none of it, practically, soaks away where it is not wanted. The principal advantage of the Skinner sprinkling system is, if I am correct, that the man who runs the engine can direct the water to any point and in any amount; whereas with the furrow system it requires several men to direct the water and get it where it is needed most and not use too much. The ground should be thoroughly underdrained with tiles with either system, in order to get rid of the overplus of water either from excessive rains or irrigation.

Considerable is done in some regions in Florida in the way of sub-irrigation by running the water into tiles. Now, some of the soils in Florida, especially in the drained swamps that are so suitable for celery, sometimes break up in clods as the ground does here in Ohio, and there is no way to break up these clods and get the ground friable except to wait for what we call a "summer shower." With the sprinkler system these clods can be moistened just enough to let the harrow pulverize them thoroughly; and in setting out plants you can have not only the soil but the *air* also moistened up by the sprinklers until the plants have taken root and can stand the hot sun.

I visited the Wyman plant several times. There is, all together, about 35 acres under this overhead irrigation; and I tell you it is a wonderful sight to see a veritable summer shower, cooling the air and refreshing the plants at the close of a hot summer day. The sprinkling is mostly done toward sundown, and from that time on until midnight or later. Where the water is limited, there is not nearly so much loss by evaporation as when the sprinkling is done in the daytime. When you look off toward the work of the sprinklers, and see it at just the right angle, just as the sun is going down, it is one of the most beautiful sights I ever beheld. The pressure is such from the engine that each tiny stream of water goes up in the air perhaps 12 or 15 feet; and when the pipes are turned to throw the water the greatest distance, the course of the stream is something like that of a rainbow; and the sight of ten thousand streams of water (I think there must be pretty nearly that number) curling up in the air at regular distances, each tiny raindrop flashing in the sunshine, was enough to make me want to sail my hat up in the air and and shout in regular boy fashion.

Just one thing more that recommends the sprinkling system. They claim that, when a

frosty night comes, by turning on the water they can largely obviate the danger and damage from frost. This was tried once during the winter; but at the time we had the frost (at least in some localities) there was an exceedingly cold north wind; and a cold wind seems to hurt some tender stuff almost as much as a frost. I believe, however, that the water made the damage to the growing stuff much less than it would have been without it. I feel quite certain that it may protect many plants from injury from frost, because I have seen the sprinklers at work when they seemed to throw a spray that produced a filmy mist that floated over the garden like a cloud. Both farms were shipping celery at the time I left, and, so far as I could learn, the quality was first-class, without any particular difference resulting from the respective methods of irrigation.

---

## Temperance.

---

### TAKING COURAGE WHEN YOUR ENEMY TELLS LIES ABOUT YOU.

I have always admired the *Sunday School Times*, but more than ever since they are backing so strenuously the temperance wave now sweeping over the land. I have for some time noted the outrageous falsehoods which the brewers and liquor-dealers are using, and I was wondering if the people generally would not soon begin to detect the glaring untruth and refuse to be influenced by their stories. Now see how the *Times* presents the whole matter:

#### WHY THE ENEMY GETS DESPERATE.

When the Devil can use truth effectively he does so. He is shrewd enough to resort to lies only as a desperate measure; therefore when he begins lying, those on the other side ought to feel much encouraged. There is great cause for encouragement just now in the ranks of the temperance workers. For example, the Associated Prohibition Press notes that on March 2 a special despatch to the leading papers throughout the United States stated that the United States Pure-food Expert (Dr. H. W. Wiley) had declared in an address the evening before that the man who "never takes a drink of whisky is a mollycoddle," and had advised young men to drink. In a statement given out March 5, Dr. Wiley vigorously denies the words attributed to him, and remarks, "I believe the general effect of alcohol on mankind is wholly bad. I further said that I was in theory a prohibitionist; but there were difficulties in the way of prohibition, and that the better plan would be to abolish the saloons. I did not suggest or advise our young men to drink liquor of any kind, but said it was very bad." Again, it is noted that on March 3 the *Milwaukee Sentinel* quoted the Rev. Henry Coleman, a leading prohibition worker of Milwaukee, as saying, "Prohibition does not prohibit, and you will always find that there is more liquor drunk in prohibition districts than there was before prohibition was enforced." Upon the basis of this alleged quotation the *Sentinel* preached a sermon in favor of free whisky. The next day the *Sentinel* published an absolute denial of the alleged statement from the Rev. Mr. Coleman himself. These things would not occur if the liquor interests were having an easy time of it.

Dr. Wiley has been the friend of bee-keepers, and we are all deeply interested in seeing him quoted correctly before the people.

SEABOARD  
AIR LINE RAILWAY

**WE WILL SEND TO YOU FREE.**

This handsomely illustrated, fifty-page booklet containing a most interesting description of the famous Manatee section, being a reproduction of a series of articles written by the editor of one of the leading agricultural papers in the United States after a personal investigation by him. The articles were run in serial form in his publication during the last four months, and we have embodied same in an attractive pamphlet, illustrating it with dozens of interesting and instructive scenes from actual life. This handsome piece of literature will be thoroughly enjoyed and worthy of preservation, and will be sent free, together with pamphlet containing a list of properties available in the LAND OF MANATEE upon receipt of five cents in stamps or currency to cover cost of mailing. Our supply of this booklet is limited, and if you want a copy you should not delay, but write at once.

# Painting As An Investment

**A**N outlay of money can always be divided into two classes: Expense and Investment. It is always Expense when you do not receive full value for your money.

It is an investment when you do receive full value. All paints can be classed in this manner. Some are simply expense. Others are an Investment. Some fall short of requirements. Others more than fulfill all requirements.

## Lowe Brothers "High Standard" Liquid Paint

is an Investment paint. It more than fulfills all requirements. With 35 years of experience in paint-making Lowe Brothers produce a paint that has a better covering capacity and will cover more square feet to the gallon than any other paint. Every can of "High Standard" Liquid Paint is full U. S. Standard measurement. All the ingredients used in "High Standard" Paint are the best quality obtainable. All the ingenuity, all the skill, all the best mechanical appliances are employed to make "High Standard"

Liquid Paint the best that money or brains can produce.

The "Little Blue Flag" is the Lowe Brothers emblem of quality. On every can of Paint and Varnish it means quality—and there's a special product for every need.

Write for Booklet, "Attractive Homes and How to Make Them," and Color Cards of latest fashions.

They are free for the asking.

## WANTED--A RIDER AGENT IN EACH TOWN

Model "Ranger" bicycle, furnished by us. Our agents everywhere are making money fast. Write for full particulars and special offer at once.

**NO MONEY REQUIRED** until you receive and approve of your bicycle. We ship to anyone, anywhere in the U. S. without a cent deposit in advance, prepay freight, and allow **TEN DAYS' FREE TRIAL**, during which time you may ride the bicycle and put it to any test you wish. If you are then not perfectly satisfied or do not wish to keep the bicycle you may ship it back to us at our expense and *you will not be out one cent.*

**FACTORY PRICES** We furnish the highest grade bicycles it is possible to make at one small profit above actual factory cost. You save \$10 to \$25 middlemen's profits by buying direct of us and have the manufacturer's guarantee behind your bicycle. **DO NOT BUY** a bicycle or a pair of tires from anyone at any price until you receive our catalogues and learn our unheard of *factory prices and remarkable special offers to rider agents.*

**YOU WILL BE ASTONISHED** when you receive our beautiful catalogue and study our superb models at the *wonderfully low prices* we can make for 1908. We sell the highest grade bicycles for less money than any other factory. We are satisfied with \$1.00 profit above factory cost. **BICYCLE DEALERS**, you can sell our bicycles under your own name plate at double our prices. Orders filled the day received.

**SECOND HAND BICYCLES.** We do not regularly handle second hand bicycles, but usually have a number on hand taken in trade by our Chicago retail stores. These we clear out promptly at prices ranging from \$3 to \$8 or \$10. Descriptive bargain lists mailed free.

**TIRES, COASTER-BRAKES,** single wheels, imported roller chains and pedals, **DO NOT WAIT** to write today and we will send you free by return mail our large catalogue, beautifully illustrated and containing a great fund of interesting matter and useful information; also a *wonderful proposition* on the first sample bicycle going to your town. It only costs a postal to get everything. Write it now.

1322 SOUTH FLORES ST. SAN ANTONIO, TEXAS

## ITALIAN

## Queens

and bees, and nothing but Italians. An improved superior strain is what QUIRIN-THE-QUEEN-BREEDER raises. Our stock is northern-bred and hardy. We just visited our outyards (all wintered on summer stands), and not a colony is dead to date (March 18). Some hives have lost scarcely a bee, so it appears. BROTHER BEE-KEEPER, how do you like such stock for hardiness? A party up in Maine got 50 nuclei of us several years ago. We just received a letter from him. He is after more of our bees, because last season he got 2200 pounds of honey which sold for 22 cts. per pound. Our stock is well known throughout the United States. Some of the largest yields reported can be traced to our stock. Over 20 years a breeder. Free circular and testimonials. Price of stock as below.

| Prices of Queens before July. | 1      | 6      | 12      |
|-------------------------------|--------|--------|---------|
| Select queens . . . . .       | \$1 00 | \$5 00 | \$ 9 00 |
| Tested queens . . . . .       | 1 50   | 8 00   | 15 00   |
| Select tested queens . . . .  | 2 00   | 10 00  | 18 00   |
| Breeders . . . . .            | 4 00   |        |         |
| Golden five-band breeders . . | 6 00   |        |         |
| Two-comb nuclei, no queen . . | 2 50   | 14 00  | 25 00   |
| Three-comb nuclei, no queen . | 3 50   | 20 00  | 35 00   |
| Full colonies on eight frames | 6 00   | 30 00  |         |

ADD the price of whatever grade of queen is wanted, with nuclei or colonies; nuclei ready about May 1st to 10th; can furnish bees on Danzenbaker or L. frames; pure mating and safe arrival guaranteed. We employ 400 to 500 swarms in queen-rearing, and expect to keep 500 to 1000 queens on hand ready to mail. Our Northern-bred bees are hardy, yet gentle; they will give you results. Address all orders to

## The Time To Place Your Order for **QUEENS**

for spring delivery is here. Order now (with partial payment if not convenient to send all) and state when you want delivery. When ready for the queens, send the remainder. By so doing I shall be able to handle your order without the usual delays incident to the rush orders when the season is on.

|                            |        |        |         |
|----------------------------|--------|--------|---------|
|                            | 1      | 6      | 12      |
| Untested, in May and June, | \$1.00 | \$5.50 | \$10.00 |
| Untested, after July 1     | .75    | 4.00   | 7.50    |

Selects, 25 cents extra. Tested, May and June, \$1.50; after July 1, \$1.25. Nuclei and full colonies ready May 1. Catalog for 1908 free. Send for one.

**GEO. W. BARNES, Box 340, NORWALK, O.**

## Westwood Red-clover Queens

Are the bees that got the honey in 1907. Better try them for 1908. Nuclei and full colonies a specialty. Price list on application.

**HENRY SHAFFER, 2860 Harrison Ave., Sta. L, Cincinnati, O.**

## PHARR'S GOLDENS

took first prize at three exhibits in 1907. We also breed Carniolans, three-banded Italians, and Caucasians, bred in separate yards and from the best breeders obtainable; guarantee safe delivery and fair treatment. Untested, \$1; tested, \$1.25. Address New Century Queen-rearing Co., Bercair, Tex. John W. Pharr, Prop.

## W. H. Laws

is again on hand for the coming season with a larger stock of queens than ever before. He sold 400 queens to a New Mexico producer last May who wrote, "Your stock is far ahead of those Eastern queens I have been buying," and has placed his order for 1000 more of the Law queens to be delivered in May and June coming.

Others write that, if they had purchased all Laws queens, their crop of honey would have been doubled. Testimonials enough to fill this book. If you are going to improve your stock, had you not better investigate?

Single queen, \$1.00; dozen, \$10.00; breeders, the best, each, \$5.00. **W. H. LAWS, Beeville, Bee Co., Texas.**

## ITALIAN QUEENS BY RETURN MAIL OR MONEY REFUNDED.

Warranted, \$1.00 each, six for \$5.00; tested, \$1.50 each.

Circular free.

**D. J. BLOCHER, PEARL CITY, ILL.**

## FOR SALE=Queens

of my famous Red-clover stock. Untested, 50 cts. each; select untested, 75 cts. each; tested, \$1 each. Nuclei, \$1 per frame. Golden queens, same price. **H A ROSS, 1709 Upper Second St., Evansville, Ind.**

# Queens Queens

of the

## FINEST POSSIBLE BREEDING

BRED BY

**F. J. WARDELL,**  
**UHRICHSVILLE, OHIO, U. S. A.**

After many years' experience as head queen-breeder for The A. I. Root Co., I am now breeding bees at the above address. My stock is equal to any now advertised, and my long experience enables me to judge very accurately the value of any strain. Mine is the celebrated red-clover stock, which has given so much satisfaction to thousands of buyers for a number of years past. If you desire something very select for breeding purposes, write to me, stating your wants, and the same will be supplied. I have no cheap or inferior queens to sell. My prices for the season are as follows:

|                                  | May to June.      |
|----------------------------------|-------------------|
| Untested queen . . . . .         | \$1.25            |
| Select untested queen . . . . .  | 1.50              |
| Tested queen . . . . .           | 2.50              |
| Select tested queen . . . . .    | 3.50              |
| Breeding queens . . . . .        | 6.00              |
| Select breeding queens . . . . . | 9.00              |
| Extra select . . . . .           | 1 year old, 12.00 |

No untested queens sent before May 15; but to secure your queens early in the season it is necessary to order now. Absolutely, all orders filled in rotation.

# 5000 QUEENS

of the famous 3-banded LONG-TONGUE RED-CLOVER STRAIN OF ITALIAN BEES is what I want to sell this season.

My bees GATHER HONEY if there is any to get; ARE LITTLE inclined to swarm and sting, they please such people as The A. I. Root Co., R. F. Holtermann, W. Z. Hutchinson, Morley Pettit, etc., and if they don't please you, send in your kick.

Queens of all grades now ready.

# BARGAINS IN BEE-FIXTURES.

We offer at reduced prices quite a list of goods located at various points, and chiefly of styles not at present listed in our catalog. You may find here something which you can take to advantage. Orders may be sent direct to Medina, or in some cases direct to the dealer or branch house where the goods are on hand. In ordering, be sure to mention that you saw it in "Bargain Notice" in GLEANINGS.

THE A. I. ROOT CO., Medina, O.

## EXTRACTORS.

At Apopka, Orange Co., Fla., one six-frame Cowan extractor for L. frame, which has been used in all about 30 days; was sold five years ago, and is the old-style chain reversing type; sold new for \$30.00. We offer this for \$17.00, free on board at shipping-point.

At Medina, O., three eight-frame Root Automatic extractors which have been to Cuba and returned; have been somewhat rusted and corroded by salt air; well cleaned up, and in good condition. With ordinary hand-power gear will sell at \$32.00 each; regular price \$40.00. With power gear and belt complete, without engine, \$36.00; regular price, \$45.00.

No. 4 Novice extractors at Mechanic Falls, Me.; also at Chicago, Ill.; also Des Moines, Iowa; new stock, but an over supply, offered at \$7.75 each; regular price, \$8.50.

No. 15 Cowan extractor at Mechanic Falls, Me.; new machines in good condition as put out three years ago; offered at \$11.00 each.

DADANT UNCAPPING-CAN at St. Louis, Mo., and in New York city; offered at \$7.75 each; new stock in good condition, somewhat shop-worn.

GERMAN WAX-PRESS at St. Louis, Mo., and in New York city; also at Medina, O. These are not of the latest pattern, but good machines in good condition; offered at \$9.00 each; regular price, \$12.00.

BOARDMAN SOLAR WAX-EXTRACTOR at Des Moines, Iowa, and at New York city, in good condition at \$6.00; Regular price, \$7.50. Also at New York a Doolittle solar wax-extractor at \$3.25.

## PARTS OF HIVES.

DANZ. NAILLESS COVERS, made of three pieces, tongued and put together with paint in joints and crate-staples over joint at each end, then a galvanized channel steel cleat at each end; the same style as our metal-bound super-cover, only made of  $\frac{1}{8}$ -in. lumber. Special price to close out, 20 cts. for 8-frame; 22 cts. 10-frame, which is  $\frac{1}{2}$  regular price.

The A. I. Root Co., Syracuse, N. Y., 30 D-8 and 68 D-10  
The A. I. Root Co., Philadelphia, Pa. 70 D-8 and 500 D-10

COMBINED BOTTOM AND HIVE-STAND. This is a very convenient and serviceable hive-bottom which sold at the same price as the hive-cover, or was

included instead of the regular bottom at 5 cts. per hive extra; can be had from the following places in 8 or 10 frame size as listed, at the price of the regular bottom, in lots of 5 or more, 20 cts. each, 8-frame; 22 cts. each, 10 frame.

M. H. Hunt & Son, Redford, Mich., 30 C-8 and 20 10  
The A. I. Root Co., Syracuse, N. Y., 30 C-8 and 100 C-10  
The A. I. Root Co., Philadelphia, Pa., 100 C-8 and 10 C-10  
The A. I. Root Co., Chicago, Ill. . . . 80 C-8 and 80 C-10  
The A. I. Root Co., Medina, O. . . . 100 C-8 and 100 C-10  
John Nebel & Son, High Hill, Mo., 50 C-8

DOVETAILED T SUPER for producing honey in  $\frac{1}{4}$  sections supported on T tins. These are mostly provided with T fences for the  $4\frac{1}{2} \times 1\frac{1}{2}$  plain section.

Buck & Wilson, Augusta, Kans., 25 4TP-8; price 50 cts. each for the lot, or 60 cts. each in lots of 5.

The A. I. Root Co., Chicago, Ill., 50 2TP-8.

The A. I. Root Co., Philadelphia, Pa., 25 2TP-8 and 10 Hilton Dov. T supers, which are the same with thumb-screws in one side.

The A. I. Root Co., St. Paul, Minn., 10 2TP-8 and 10 2TS-8 Hilton Dov. T supers.

Price 35 cts. each in lots of 5 or over.

THICK-TOP STAPLE-SPACED FRAMES, L size, with  $4\frac{1}{2} \times \frac{1}{8}$ -inch end-bars, at \$2.25 per 100, or \$10.00 per box of 500.

The A. I. Root Co., Philadelphia, Pa., 4000 frames.

The A. I. Root Company, Chicago, Ill., 2500 frames.

At both points are also some of the same style, jump-bottom depth, at 25 cts. per 100 extra.

ALL-WOOD FRAMES, regular style, with The A. I. Root Co., Philadelphia, Pa., 4000; price \$1.80 per 100, or \$7.50 per phase of 500.

HOFFMAN FRAMES with square-edge end-bars, otherwise regular; price \$2.50 per 100.

Blanke & Hawk Supply Co., St. Louis, Mo., 300 frames.

The A. I. Root Co., Philadelphia, Pa. . . . 1700 frames.

CHAFF DIVISION-BOARDS, regular pattern; price in flat, 10 cts. each; nailed, 20 cts. each, in lots of 10 or more.

Blanke & Hawk, St. Louis, Mo., 50 nailed at 20 cts. ea.

The A. I. Root Co., Philadelphia, Pa., 200 " at 20 cts. ea.

W. S. Pouder, Indianapolis, Ind., 60 nailed at 20 cts. ea.

M. H. Hunt & Son, Redford, Mich., 75 in flat, 10 cts. ea.

TEN-FRAME DOVETAILED HIVE-BODIES with molded-top Hoffman frames; no division-board; listed as 6-10

With The A. I. Root Co., New York city, 300, offered in regular crates of 5 at 60 cts. each, or \$3.00 per crate; lots of 50 or more at 50 cts.

The A. I. Root Co., St. Paul, Minn., have a lot of Danz. hives and supers; also ten-frame Dovetailed hives, nailed and painted, second hand, in good condition, which they will sell at a special price. Correspond direct with them.

STANDARD ROOT SMOKERS. We have here at Medina something less than 100 of these smokers, which have been to Cuba and returned. They are somewhat rusted but may be made serviceable by one not too particular for appearances. Will sell them at 50 cts. each, or \$5.00 per dozen; by mail, 25 cts. each extra.

## Classified Advertisements.

Notices will be inserted in these classified columns at 25 cents per line. Advertisements intended for this department can not be less than two lines, and should not exceed five lines, and you must say you want your advertisement in the classified columns or we will not be responsible for errors.

# The Hand System

TO satisfy a number of customers we are now making hives to suit the above system, just as the inventor himself uses them. These are not listed in our regular spring catalog, and are not kept in stock at any of our agencies. All orders will be filled from Medina. If ordered early enough, however, they can be forwarded to any one of our branches for redistribution. If you are going to try a few of these hives the coming season, we earnestly urge you to order early before the rush season comes on.

### PRICE LIST OF HAND DIVISIONAL HIVE AND PARTS.

We have had numerous calls for divisional hives just as Mr. Hand uses them. We will not list them in our catalog for the coming season, but will make them up to supply on special order, to those who desire to try them, at prices in table below. The outside dimensions being nearly the same as the regular Dovetailed hive, the regular covers and bottoms may be used.

Each section is 19½ in. long, 5½ in. deep outside; upper portion of side removable with clamps to hold it in place. Sections used are 4¼x4¼x1½ plain, split three sides. Furnished in both eight and ten frame size.

Hand brood or extracting section, including the frames, springs, clamps, and nails; no foundation .....  
Hand brood or extracting section, including the frames, springs, clamps, and 1-inch foundation starters .....  
Hand brood or extracting section, including the frames, springs, clamps, and full sheets comb foundation .....  
Hand comb-honey section, including section-frames, and fences; no sections or foundation starters .....  
Hand comb-honey section, including section-frames, fences, sections, and full sheets foundation .....  
Hand four-section hive including two brood and two comb-honey sections; no sections or foundation starters .....  
Hand four-section hive including two brood and two comb-honey sections with sections and full sheets foundation .....  
Hand sectional super, no inside fixtures, including clamps, nails, and flat tins .....

**The A. I. Root Company, Medina, Ohio**

The reports of wintering of the bees over the country are generally good. New York State has sent in some unfavorable reports. Along about the middle of March there was not an unfavorable report; but the expected warm weather was somewhat delayed. It has now, April 24, come, and the bees will probably make good for lost time.

#### MAPLE SYRUP.

We have a good supply of very choice maple syrup which we can supply at \$1.00 per gal.; 6 gal. at 95c; 20 gal. or over, 90c. Will be pleased to hear from those interested. Maple sugar is not so plentiful, and we can not offer this at less than 15c per lb. for best; 13c for fair to choice.

#### CARTONS FOR OUNCE CAKES OF BEESWAX.

We can supply cartons for one-ounce cakes of beeswax, printed with name and address blank, at 35 cts. per 100; 250 for 80 cts.; 500 for \$1.50; 1000 for \$2.75; by mail, 15 cts. per 100 extra. These prices will also include the large carton to contain 32 of the small ones. The complete package weighs 2 lbs., and, when filled, sells to the dealer at \$1.00. They retail the cakes at 5 cts. each. Retained molds for molding ounce cakes cost 35 cts. per dozen; by mail, 40 cts.; for two-ounce cakes, 40 cts.; by mail, 50. We do not have cartons to fit the two-ounce cakes. To print your name and address on the cartons will add, 250 or less, 50 cts.; 500, 75 cts.; 1000, \$1.00.

#### DR. MILLER SPLINTS.

We have often had calls for wood splints for use with foundation in brood-frames to prevent sagging, as used and recommended by Dr. C. C. Miller. We have usually made them by sawing them out, and wasted more than three-fourths of the wood in sawdust. We have hit upon a plan of slicing them, thereby saving all the wood, and cheapening the process as well. We can furnish them  $\frac{3}{4}$  inches long for L. frames at 50 cts. per 1000 by mail; 40 cts. shipped with other goods. Small lots at 10 cts. per 100 postpaid. Other lengths can be furnished as well. If shorter, same price in 1000 lots. If longer, add fifty per cent up to 12 inches long.

#### SECOND-HAND FOUNDATION-MILLS.

We have to offer the following second-hand foundation-mills in good condition. We shall be pleased to hear from any one interested. To such we can send a small sample of comb foundation representing the kind of work produced by the particular machine you enquire about.

No. 079.— $6 \times 2\frac{1}{4}$ -inch hex. cell thin-super mill, in very good condition. Price \$12.00.

No. 078.— $6 \times 2\frac{1}{4}$ -inch hex. cell thin-super mill, in good condition. Price \$12.00.

No. 088.— $6 \times 2\frac{1}{4}$ -inch hex. cell extra-thin-super mill, in good condition. Price \$12.00.

No. 075.— $2 \times 9$  hex., very old style, on frame with wood base; in fair condition. Price \$10.00.

No. 085.— $2\frac{1}{2} \times 6$  hex. thin-super mill, in good condition. Price \$12.00.

No. 086.— $2\frac{1}{2} \times 6$  hex. extra-thin-super mill in extra-good condition. Price \$15.00.

No. 096.— $2\frac{1}{2} \times 10$  hex. light-brood mill; almost new; in fine condition. Price \$20.00.

No. 097.— $2\frac{1}{2} \times 10$  hex. light-brood mill; in fine condition. Price \$18.00.

No. 077.— $10 \times 2$  inch-medium brood round cell, old-style frame, in good condition. Price \$14.00.

No. 092.— $6 \times 2\frac{1}{4}$ -inch hex. cell extra-thin-super mill, in fine condition. Price \$15.00.

No. 2275.— $6 \times 2\frac{1}{4}$ -inch hex. cell extra-thin-super mill, in good condition. Price \$13.00.

#### SIMPLEX HONEY-JARS.

The factory have assured us that we may again secure this popular honey-jar in several sizes, including the one holding one pound of honey. We have ordered a fresh supply, and expect to have them in stock this next month. They will be packed in reshipping-cases of two dozen each, and the price will be \$1.10 per case; 6 cases, \$6.30.

#### NO. 25 HONEY-JARS.

During the past year we have had an unusual amount of trouble with breakage of this jar, even in the reshipping-cases packed with corrugated paper. The breakage occurred either in the porcelain cap or the top rim of the jar where the cap rests. We find we can get this same jar with lacquered tin cap without the center being cut out. This cap is lined with waxed paper wad, which seals tight on the top edge of the jar. This style of cap not only does away with breakage almost entirely, but enables us to furnish the jar at a lower price. We are not yet supplied with the new stock, but expect to have them this month at the following price. They will be packed as usual, two dozen in reshipping partitioned cases. No. 25 jars, tin cap lined, 90 cts. per case; 6 cases, \$5.10. We can still furnish from stock the usual style of No. 25 with porcelain caps at \$1.10 per case; 6 cases, \$6.30.

#### A BARGAIN IN DANZ. SUPERS AND SHIPPING-CASES.

We offer at a special bargain 120 Danzenbaker ten-frame supers, nailed and painted, filled with section-holders, Hyde-Scholl "M" fences, sections with full sheets of foundation. They have been used, but are nearly new and in good condition. Such supers new are listed in our catalog at \$1.75 each, yet we offer this lot crated and on board cars at Floresville, Texas, at 50 cts. each for the lot, and will throw in 1000  $4 \times 5$  sections to make good any in the lot which may be broken or missing. In lots of not less than ten the price would be 60 cts. each; 50 at 55 cts. each as they are crated and loaded on cars. There are also 400 shipping-cases to hold 20  $4 \times 5$  sections in the crates as shipped from the factory, which we would sell at \$5.00 per crate of 50, or \$9.00 per 100 for the lot—that is, \$140 cash for goods worth new at carload prices over \$340. This surely is a bargain for any one desiring to produce fancy comb honey with equipment that can not be excelled for the purpose. They are not in the right locality for comb-honey production, but should work excellently in some other locality. Send your orders here to Medina.

### Special Notices by A. I. Root.

#### PHILO'S POULTRY-HOUSE FOR THOSE WHO LIVE IN TOWNS AND CITIES.

We expected to give a picture of this structure in the present issue, but the cut came a little too late. Now you may all look forward to something that is exceedingly interesting and unique in our next issue, in the line of poultry-keeping in town and cities.

#### THE FIRELESS BROODER UP TO DATE.

It is no more than fair that I should state that I have lost six chicks out of my twenty-five in the fireless brooder, up to date, April 24. But I must also confess that I did not follow Philo's directions given in his book. When we had quite a freeze outdoors I felt sorry for them, and put them near the steam-pipes in the greenhouse. Of course, they got up close to the hot pipes, and I thought they would be all right. The rest of them are now, however, running all over outdoors, under the cherry-trees that are now in full bloom, and they seem to be doing finely. I am inclined to think I "killed them with kindness," for I had no loss at all in Florida (or almost none) except some that were killed by accident.

**SPROUTED GRAINS FOR POULTRY AND OTHER DOMESTIC ANIMALS, BY PROF. FORBES, OF THE DEPARTMENT OF NUTRITION, OHIO EXPERIMENT STATION, WOOSTER.**

I take pleasure in submitting the following, from our Ohio Experiment Station, in regard to the food value of sprouted grains—see page 512. Of course, we shall have to wait for some accurate experiments before coming to a conclusion in regard to the matter. But it would seem from the above that sprouted grains are a benefit in giving the animals variety, even if they do not result in a great saving in the expense of grain feed. We are in hopes there may be at least some truth in the claim that there is a great saving in the amount of grain fed in this way to the poultry.

WOOSTER, O., April 17, 1908.  
Mr. Root:—Your inquiry regarding sprouted grain has been referred to me for reply. There has recently been organized here at Wooster a department of nutrition for the study of just such problems as the one you suggest. I have been interested for several years in just the point you raise, but have not had opportunity to work it out. I intend to take it up at an early date, however. Several years ago there was a firm at the stock-yards in Chicago which sold a germinator for use with grain intended for feeding, and they maintained a continuous demonstration of the appliance, using several kinds of animals, mostly old "skates" of one sort and another, such as do not usually get any valuable feed. They had no difficulty in getting these old animals rolling fat. They put out an extravagant and ignorant booklet advertising the germinator, but went out of business some time ago. I wrote a number of letters a couple of years ago trying to get hold of one of their germinators, but could get no trace of them.

There is surely an increased digestibility with sprouting, and there is also a change of phosphorus from various forms to lecithin, a compound characteristic of structures in which intense vital activity has been provided for, and which physiologists consider to be of great nutritive value. I have no definite information on the subject of feed value, but would judge that the improvement might pay for the handling where grain is expensive. I shall go into the matter at an early date.  
E. B. FORBES.

**SAVING CHICKENS THAT WOULD OTHERWISE HAVE DIED IN THE SHELL.**

Quite a good deal of interest seems called forth in regard to this new discovery. It is not exactly new, however, because many people practice more or less helping chickens out of the shell toward the close of the hatch. I believe the manufacturers of incubators claim it does not pay. There can be no objection, however, to experimenting with eggs that are not hatched before the 22d day. Philo thinks that many chicks fail to break the shell for lack of air—probably because the shell is too heavy, and may be because the pores are more or less closed. He recommends making an opening with the point of a knife into the air cell. This gives the chick air, and as a matter of course, more strength. Then if the egg is wrapped in a wet cloth to soften the shell, the chicken will ordinarily succeed in getting out. If it does not, you can carefully break away more of the shell. Two years ago I saved several chickens that did not seem to have the strength to get out after they had pierced the shell. After the incubator is opened, the glutinous matter dries down so as to fetter the chicks, seemingly. I have soaked chicken and all in quite warm water, washed them up clean, put them back in the incubator, wrapped them in a wet cloth, and succeeded, I believe, almost every time. One of the boys who was running the baby-chicken establishments I have mentioned said he had also saved chicks in this way; but it took so much time to fuss with them that it was

something of a question whether it paid or not. Where you have nothing else to do I think I would try to save all the eggs in this way where either hen or incubator seems to fail.

**Convention Notices.**

**RESOLUTIONS OF RESPECT.**

Whereas, There has passed from this life our able and gifted member, Henry Alley, whose long experience, and genius and skill, caused him to be widely known and recognized as an authority in his art, therefore it is

**RESOLVED** That in his death the Massachusetts Society of Bee-keepers, and apiculture in general, bear a loss that will be keenly felt; and it is further

**RESOLVED** That we tender to his family our deep and heartfelt sympathy, and that a copy of these resolutions be sent to them and also placed on our records as a tribute to his memory.  
X. A. REED, Sec  
Belmont, Mass.

A reporter for the coming National convention is one of the things to be looked after with care. Possibly not more than ten per cent of the members can attend the convention; the rest must depend upon a printed report of what was said and done. They pay their money to support the Association, and we owe it to them to give them a complete and accurate report. The best reporter that we have ever employed is Mr. Geo. Angus, of Toronto, Ontario, Canada. He has had a lot of experience in reporting bee conventions, has caught on to the technical terms, and furnishes a report all correctly worded, and ready to be handed over to the printer, without correction. I am pleased to be able to announce that we have secured his services for the coming convention at Detroit, and those who find it impossible to attend may comfort themselves in knowing that they can sit at their own firesides and read exactly what was said and done.  
W. Z. HUTCHINSON, Sec. N. B. K. A.

# Are You Looking Ahead?

The well-to-do farmers and stockmen of to-day got their start in the West in the eighties. They located in a new country, but conditions were not as favorable then as they are to-day.

To-day's opportunities for success and independence are also in the West; they are along the new line to the Pacific Coast in the Dakotas, Montana, Idaho, and Washington. Land there is cheap; homestead lands are still plentiful; good crops and markets are assured; railroad facilities are good.

Regular passenger and freight trains are now operated as far west as Lombard, Montana, on the **Pacific Coast Extension** of the

## CHICAGO MILWAUKEE *and* ST. PAUL RAILWAY

On March 17 and April 7 over one thousand homeseekers bought tickets to points on the new line in the Dakotas and Montana. During March four hundred cars of homeseekers' outfits from points east were unloaded at various stations on this new line. These people are looking ahead; they are taking advantage of the opportunities; they will be the well-to-do settlers of the future.

Send for free descriptive books. They will interest the farmer, the stockman, the merchant, the fruit-grower, the workingman, the professional man.

# ARE THEY WORTH SAVING?

## Mr. Haviland Saves 28 Chicks in One Hatch.

Fully one-third of all the chickens ready to hatch die in the shell. After 30 years' study and practice we have discovered a simple way to save every chick that is fully developed and ready to hatch, whether the egg is pipped or not. This, we believe, is one of the lost arts of the ancient Egyptians. It takes but a minute to save a chick, and no skill required. Note Mr. Haviland's success:

Dear Sirs:—  
I received my copy of the Philo System at noon, the last

Brookville, Md., Feb. 27, 1908.

hour of the 21st day for my incubator, containing 172 fertile eggs. About 100 were out of the shell and about 30 of the remainder were still alive, some pipped. According to directions with our hot-air machine these were worthless. We immediately proceeded according to "A Trick of the Trade" in your book and hatched them all, even one that showed signs of life after laying in a garbage-pail for some time. We still have 128 chicks three days old; lost but two. Many of the eggs were three or four weeks old when set.

Respectfully,

E. W. HAVILAND.

## \$200 IN SIX MONTHS FROM 20 HENS

To the average poultryman that would seem impossible, and when we tell you that we have actually done a \$500.00 poultry business with 20 hens on a corner in the city garden, 30 feet wide by 40 feet long, we are simply stating facts. It would not be possible to get such returns by any of the systems of poultry-keeping recommended and practiced by the American people, still it is an easy matter when the new PHILO SYSTEM is adopted.

### The Philo System is Unlike all other Ways of Keeping Poultry

and in many respects is just the reverse, accomplishing things in poultry work that have always been considered impossible, and getting unheard-of results that are hard to believe without seeing; however, the facts remain the same and we can prove to you every word of the above statement.

### The New System Covers all Branches of the Work Necessary for Success

from selecting the breeders to marketing the product. It tells how to get eggs that will hatch, how to hatch nearly every egg, and how to raise nearly all the chicks hatched. It gives complete plans in detail how to make every thing necessary to run the business, and at less than half the cost required to handle the poultry business in any other manner. There is nothing complicated about the work, and any man or woman that can handle a saw and hammer can do the work.

### Two-pound Broilers in Eight Weeks

are raised in a space of less than a square foot to the broiler without any loss, and the broilers are of the very best quality, bringing here three cents per pound above the highest market price.

### Our Six Months' Old Pullets are Laying at the Rate of 24 Eggs Each Per Month

in a space of two square feet for each. No green cut bone of any description is fed, and the food used is inexpensive as compared with food others are using.

Our new book, the Philo System of Progressive Poultry Keeping, gives full particulars regarding these wonderful discoveries with simple, easy-to-understand directions that

are right to the point, and 15 pages of illustrations showing all branches of the work from start to finish.

### Our New Brooder Saves Two Cents on Each Chicken

No lamp required. No danger of chilling, overheating, or burning up the chickens as with brooders using lamps or any kind of fire. They also keep all lice off the chickens automatically, or kill any that may be on when placed in the brooder. Our book gives full plans and the right to make and use them. One can be easily made in an hour at a cost of 25 to 50 cents.

Dear Sir:—  
I am well pleased with your system in poultry-keeping. We have more than doubled our egg production.

Yours truly,

J. C. THAYER.

Gentlemen:—  
Some time ago I ordered your book, Philo System, and your paper. Want to say I am highly pleased with them. Never in my life have I received so much for so little money. It is a very comprehensive treatise indeed. Your methods are so simple that a child might follow them.

Yours truly,

J. BERT MCCONNELL

Gentlemen:—  
Your publication, the Philo System, at hand, and after careful comparison, must say that without doubt or hesitation that more boiled-down, good common sense and natural facts and instruction are condensed in the pages of your book than in all I have tried (to learn) and read the date.

Yours with best wishes, GEO. A. WOLFE.

Dear Sir:—  
Your book came to hand and I must say I am very much pleased with it. It is far the best book I have seen on poultry. The ideas set forth in the book, which are the results of your experimenting, certainly show that you are a little in advance of others in this work.

Common Era, Ill., March 19, 1908.

I have built several of the brooders as described by Mr. Philo, and at present time have young chicks, a week old, outdoors, healthy and strong, without being warmed by any artificial heat.

Yours respectfully, WILSON BROOKS.

Call at our warehouse and yards at Chicago and see the lumber we are offering and you will recognize that it is all we say of it. Make your own selection and see it loaded. It is not necessary to come to Chicago, however, unless you wish to. **We can fill your order by mail with just what you want and guarantee you absolute satisfaction.** Ours is the largest direct to the

consumer lumber headquarters in the world. We sell millions of feet annually. Orders filled from every part of the United States. No matter where you live you can save money by supplying your building wants here.

We do not figure fancy prices, but quote figures that command your patronage. Whether your order is large or small we can save you money on it. Our tremendous business of millions of dollars annually is your best guarantee of complete satisfaction of every purchase made from us. In our enormous stock of new lumber of every kind we have just what you need for every purpose. Don't buy a stick of material until you get our prices. We offer you everything in the lumber and building supply line needed for residences, farm homes, stores, churches, barns, outbuildings of every kind, sidewalks and fencing. In short any kind of a structure requiring lumber, at from 30 to 60 per cent less than your local dealers or lumber yards ask for it.

## IMPORTANT! Send Us Your Lumber Bill For Our Estimate

Make up a list of what you need. Send it to us for our price. If you are putting up a building of any kind whatsoever let us figure with you. **Our prices talk louder than words.** Have your carpenter or contractor send us your list of what is needed if he has charge of your building. Don't pay exorbitant prices to the lumber trust with their long line of lumber yards all over the country. Don't let the local dealer soak you with his heavy profit. Remember, Chicago House Wrecking Company buys millions of feet of lumber under circumstances of forced sales which means sacrificed prices and enables us to sell even as low as cost without loss. You take no chances in dealing with the Chicago House Wrecking Company. Whether for \$100,000 your order will be filled carefully. Our lumber and supplies are guaranteed exactly as represented. If you have no need for a whole carload yourself get your neighbors to club in with you. By buying a carload you can save all kinds of money on freight charges.

We have railroad trains running through our main warehouses and buildings and can load a car to good advantage to you. You can include in this same car, pipe, plumbing material, roofing, wire, fencing, furniture, hardware and merchandise of every kind.

We also furnish you building and barn plans absolutely free upon request. Write us for any information or advice you want and we will have our staff of architects answer every inquiry promptly. Our free book of plans is sent if you mention this paper. We simplify your building proposition.

Our business demands quick action. We must keep our stocks moving. This means prompt shipment—no annoying delays. Let us help you lay out your plans. We will relieve you of every detail. That is what our Special Builder Service is for. Be sure and send us your lumber bill for our estimate. Feel free to write for anything you want to know along the line of building supplies, furnishings, etc.

## Honey Markets.

The prices listed below are intended to represent, as nearly as possible, the average market prices at which honey and beeswax are selling at the time of the report in the city mentioned. Unless otherwise stated, this is the price at which sales are being made by commission merchants or by producers direct, to the retail merchant. When sales are made by commission merchants, the usual commission (from five to ten per cent), cartage, and freight will be deducted, and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage, and other charges, are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

### EASTERN GRADING-RULES FOR COMB HONEY.

**FANCY.**—All sections well filled, combs straight, firmly attached to all four sides, the combs unsoiled by travel-stain or otherwise; all the cells sealed except an occasional one, the outside surface of the wood well scraped of propolis.

A No. 1.—All sections well filled except the row of cells next to the wood; combs straight; one-eighth part of comb surface soiled, or the entire surface slightly soiled; the outside surface of the wood well scraped of propolis.

No. 1.—All sections well filled except the row of cells next to the wood; combs comparatively even; one-eighth part of comb surface soiled, or the entire surface slightly soiled.

No. 2.—Three-fourths of the total surface must be filled and sealed.

No. 3.—Must weigh at least half as much as a full-weight section.

In addition to this the honey is to be classified according to color, using the terms white, amber, and dark; that is, there will be "Fancy White," "No. 1 Dark," etc.

### NEW COMB-HONEY GRADING-RULES ADOPTED BY THE COLORADO STATE BEE-KEEPERS' ASSOCIATION.

**No. 1 WHITE.**—Sections to be well filled and evenly capped except the outside row, next to the wood; honey white or slightly amber, comb and cappings white, and not projecting beyond the wood; wood to be well cleaned; cases of separated honey to average 21 pounds net per case of 24 sections, no section in this grade to weigh less than 13½ ounces.

Cases of half-separated honey to average not less than 22 pounds net per case of 24 sections.

Cases of unseparated honey to average not less than 23 pounds net per case of 24 sections.

**No. 1 LIGHT AMBER.**—Sections to be well filled and evenly capped, except the outside row, next to the wood; honey white or light amber; comb and cappings from white to off color, but not dark; comb not projecting beyond the wood; wood to be well cleaned.

Cases of separated honey to average 21 pounds net per case of 24 sections; no section in this grade to weigh less than 13½ ounces.

Cases of half-separated honey to average not less than 22 pounds net per case of 24 sections.

Cases of unseparated honey to average not less than 23 pounds net per case of 24 sections.

**No. 2.**—This includes all white honey, and amber honey not included in the above grades; sections to be fairly well filled and capped, no more than 25 uncapped cells, exclusive of outside row, permitted in this grade; wood to be well cleaned, no section in this grade to weigh less than 12 ounces.

Cases of separated honey to average not less than 19 pounds net.

Cases of half-separated honey to average not less than 20 lbs. net per case of 24 sections.

Cases of unseparated honey to average not less than 21 lbs. net per case of 24 sections.

**INDIANAPOLIS.**—Jobbers are fairly well stocked, but very little honey is being offered by producers. Best grade of extracted honey is in good demand, but comb honey is finding slow sale. Jobbers are offering the following prices, delivered here: No. 1 and fancy comb, 15 to 17; extracted white clover, 8 to 9; amber, in barrels, 6 to 6½. Beeswax, 28 cts. cash or 30 in exchange for merchandise.

May 5.

WALTER S. POWDER,  
Indianapolis, Ind.

**LIVERPOOL.**—The honey market is steady and quiet, but stocks are not large. Fine quality meets with fair demand, but low grades are almost entirely neglected. We quote: Chilean, 4 to 6½; Peruvian, 3½ to 5½; California, 7½ to 9; Jamaican, 4 to 5½; Haiti, 6½ to 6¾. Beeswax is steady—African, 27 to 30; American, 30 to 33; West Indian, 27 to 32; Chilean, 30 to 36; Jamaican, 34 to 35.

April 11.

TAYLOR & CO.,  
7 Tithebarn St., Liverpool.

**CINCINNATI.**—The conditions of the honey market are not satisfactory, as there is no consumptive demand for either comb or extracted honey. Lower prices are no inducement. We must await the revival of business in general, which, no doubt, will be as soon as the weather settles. Quote our fancy water-white honey for table use at from 9 to 10, according to the quantity purchased. Amber extracted honey in barrels brings 5½ to 7, the price depending on the quality and quantity. There is an abundance of beeswax, for which we are paying 30 cts. in cash and 32 in trade for choice yellow, delivered here, free from dirt.

THE FRED W. MUTH CO.,  
Cincinnati, O.

April 14.

**PHILADELPHIA.**—The call for both comb and extracted honey has fallen off considerably in the last two weeks. Quite a few job lots on the market, which parties will sell at almost any reasonable offer. This makes the prices very unsteady. We quote: Fancy white comb honey, 17 to 18; No. 1, 15 to 16; amber, 13 to 14; extracted honey, fancy white, 8 to 9; amber, 6 to 7. We do not handle on commission.

WM. A. SELSER,  
10 Vine St., Philadelphia, Pa.

April 24.

**BUFFALO.**—There has been no change in the price of honey since last quoted. The demand is fair for pure white comb and good No. 1 buckwheat comb. We think that about all in the honey in the market will be cleaned up before the new crop is ready.

W. C. TOWNSEND,  
Buffalo, N. Y.

May 11.

**ST. LOUIS.**—The honey market has not undergone any change since ours of March 20. There is no demand for honey, and the quotations are nominal as follows: Fancy white comb honey, 15 to 16; No. 1 white and amber, 13 to 14; broken and defective, less; extracted white, in cans, nominal at 8½ to 9; amber, 7 to 8; in barrels, 6½ to 7. Granulated extracted honey sells at ½ to 1 ct. per lb. less. Beeswax is firm at 28½ for prime; impure and inferior, less.

R. HARTMAN PRODUCE CO.,  
St. Louis, Mo.

April 11.

**SAN FRANCISCO.**—There is very little movement of honey at present, some grades being closely cleaned up. Prices remain stationary on all offerings. Water-white, comb, 16 to 17; white, 15; water-white, extracted, 8 to 8½; light amber, extracted, 7 to 7½; dark amber and candied, 5½ to 5¾.

Pacific Rural Press, May 2.

**KANSAS CITY.**—We have nothing to quote in the way of comb honey; but we quote extracted white at 7½. Beeswax, 25 to 27.

C. C. CLEMONS & CO.,  
Kansas City, Mo.

May 9.

**CHICAGO.**—The honey market is without volume—no special change in price of either comb or extracted. Much of the extracted from Utah will be unsold when this year's crop is harvested unless it is sold to bakers. Beeswax is steady at 30.

R. A. BURNETT & CO.,  
Chicago, Ill.

May 9.

**SCHENECTADY.**—We have had a few calls for dark extracted honey from manufacturers, but did not have any stock on hand. Of course, they will not pay fancy prices. Nothing is doing in comb honey.

CHAS. MACCULLOCH,  
Schenectady, N. Y.

May 9.

**BOSTON.**—White comb honey, fancy, 17; No. 1 white comb honey, 16; white extracted honey, 10; light amber, 9; amber, 8.

BLAKE-LEE CO.,  
134 State St., Boston, Mass.

April 10.

**ST. PAUL.**—Receipts are very light; demand moderate and prices steady. The prices below represent those obtained for shipment in small lots: Fancy white-clover comb, new, per lb., 18; fancy California, 24 combs per case, \$4.00; strained, in 60-lb. cans, per lb., 10. W. H. PATTON, Sec. Board of Trade,

April 22. St. Paul, Minn.

**DENVER.**—The market on comb honey is slow, and prices are declining. We quote to our trade, No. 1 white, per case of 24 sections, \$3.00; No. 1 light amber, \$2.85; No. 2, \$2.70; extracted, white, 8 to 9; light amber, strained, 6¾ to 7. We pay 25 cts. for clean yellow beeswax delivered here.

THE COLORADO HONEY-PRODUCERS' ASSOCIATION,  
April 22. F. RAUCHFUSS, Mgr.

THE ONLY WAY TO GET AS **GOOD** A HIVE AS A

# MUTH'S SPECIAL

IS—TO GET **ANOTHER** MUTH'S SPECIAL. 

Have a look at its picture—so you'll know it.

Notice these prices—Same as regular style of Dovetailed hives—and don't let any one pass you a grapefruit substitute when you buy a hive. Buy from us and get the real article. There is *just one* hive that

**Makes Good** Anywhere and Everywhere;  
Any Time and Every Time!

This is it—and here are the prices:

|                             | Nailed and painted | Nailed. | In flat. |         |
|-----------------------------|--------------------|---------|----------|---------|
|                             | 1                  | 1       | 5        | 10      |
| With starters:              |                    |         |          |         |
| 1-story, 8-frame.....       | \$ 1 90            | \$ 1 70 | \$ 6 50  | \$12 00 |
| 1-story, 10-frame.....      | 2 00               | 1 80    | 7 50     | 13 10   |
| With sections and starters: |                    |         |          |         |
| 1½-story, 8-frame.....      | 2 85               | 2 55    | 9 75     | 18 00   |
| 1½-story, 10-frame.....     | 3 00               | 2 70    | 10 50    | 19 50   |
| 2-story, 8-frame.....       | 3 80               | 3 30    | 13 00    | 24 00   |
| 2-story, 10-frame.....      | 4 00               | 3 50    | 14 00    | 26 00   |

A regular Dovetailed hive, but gable style of cover (*can't* blow off); rim rabbeted on inside edge of sides; honey-board; reversible and non-warping bottom; all finished like a railroad president's private car. (That's particular work, too!)

It's *worthy* of the name of *MUTH*—and that's sufficient. Better send for our catalog—it's free.

**THE FRED W. MUTH COMPANY**  
**51 WALNUT ST. THE BUSY BEE-MEN CINCINNATI, O.**

# GLEANINGS IN BEE CULTURE

Established  
1873.  
Circulation  
32,000.  
72 pages.  
Semi-  
monthly.

Devoted to Bees, Honey, and Home Interests.

Published by THE A. I. ROOT CO., Medina, Ohio.  
J. T. CALVERT, Business Manager.

\$1 per year.  
When paid  
in advance:  
2 years, \$1.50.  
3 years, \$2.00.  
5 years, \$3.00.

POSTAGE IS PREPAID by the publishers for all subscriptions in the United States, Hawaiian Islands, Philippine Islands, Guam, Porto Rico, Tutuila, Samoa, Shanghai, Canal Zone, Cuba, and Mexico. Canadian postage is 30c per year. For all other countries in the Postal Union add 60 cents per year postage.

CHANGE OF ADDRESS. When a change of address is ordered, both the new and the old address must be given. The notice should be sent two weeks before the change is to take effect.

DISCONTINUANCES. The journal is sent until orders are received for its discontinuance. We give notice just before the subscription expires, and further notice if the first is not heeded. Any subscriber whose subscription has expired, wishing his journal discontinued, will please drop us a card at once; otherwise we shall assume that he wishes his journal continued, and will pay for it soon. Any one who does not like this plan may have it stopped after the time paid for it by making his request when ordering.

HOW TO REMIT. Remittances should be sent by Draft on New York, Express-order or Money-order, payable to order of The A. I. Root Company, Medina, Ohio. Currency should be sent by Registered Letter.

AGENTS. Representatives are wanted in every city and town in the country. A liberal commission will be paid to such as engage with us. References required.

## Foreign Subscription Agents.

Foreign subscribers can save time and annoyance by placing their orders for GLEANINGS with any of the following authorized agents, at the prices shown:

PARIS, FRANCE. E. BONDONNEAU, 142 Faubourg St. Denis. *Per year, postpaid, 7½ fr.*

GOODNA, QUEENSLAND. H. L. JONES. Any Australian subscriber can order of Mr. Jones. *Per year, postpaid, 6/.*

DUNEDIN, NEW ZEALAND. ALLIANCE BOX CO., 24 Castle St. *Per year, postpaid, 6/.*

# The Hand System

TO satisfy a number of customers we are now making hives to suit the above system, just as the inventor himself uses them. These are not listed in our regular spring catalog, and are not kept in stock at any of our agencies. All orders will be filled from Medina. If ordered early enough, however, they can be forwarded to any one of our branches for redistribution. If you are going to try a few of these hives the coming season, we earnestly urge you to order early before the rush season comes on.

## PRICE LIST OF HAND DIVISIONAL HIVE AND PARTS.

We have had numerous calls for divisional hives just as Mr. Hand uses them. We will not list them in our catalog for the coming season, but will make them up to supply on special order, to those who desire to try them, at prices in table below. The outside dimensions being nearly the same as the regular Dovetailed hive, the regular covers and bottoms may be used.

| Each section is 19½ in. long, 5½ in. deep outside; upper portion of side removable with clamps to hold it in place. Sections used are 4¼x4½x1½ plain, split three sides. Furnished in both eight and ten frame size. | Designating or Short Name | Nailed and Painted Each | In Flat |         |             |

## Getting at the Root of the Matter.

*By the Bee Crank.*

The bee goes after the "inside facts" when gathering honey. It knows a good blossom from a poor one. The bee-man who expects to gather in the sweet honey of golden profits must not only go after it, but must learn how to get at its source—to distinguish between the fruitful and the barren method. There is one fundamental idea at the base of a successful bee business—the best equipment is none too good. The root of the whole matter is—use Root's goods. I handle their full line and sell at their prices—no delay, and less freight to pay. Danzenbaker and other standard hives, sections, Hoffman frames, and other requirements, ready to go on next train. Ever try one of those Danzenbaker smokers? Some of my patrons think it excels any other smoker on the market. The foundation that I am

sending out is fresh from the mill, and has that delicious odor, is soft and pliable, and easy for the bees to work. Ever see foundation that looks blue and seems hard and brittle? It is old; and, while the bees accept it and build to it, if you cut a comb of honey built on it you will think it has an oyster-shell in its center. Bees work

over fresh foundation so thin that one does not recognize it in a comb of honey. One good patron in California says in a footnote with his order, "I can get goods nearer home, but I prefer to send to you." Many of you will understand just exactly why.

Save up your beeswax for me. I am now paying 28 cents, spot cash, or 30 cents in exchange for supplies, delivered here. I have a constant demand for it.

My catalog is free.

## A WONDERFUL BOOK.

Nothing could show to better advantage the extraordinary development of American advertising than N. W. Ayer & Son's (Philadelphia) great Newspaper Annual just published. It has 1348 pages, royal octavo size, in which are sandwiched beautiful colored maps of every State and Territory, and, to an advertiser, it must be worth much more than the selling price, \$5.00. To the ordinary advertiser it must be a perfect mine of information. This knowledge is tabulated in such a way that no time is lost in seeking for the exact point desired. It contains an advertisers' telegraph code to facilitate rapid communication between advertisers and the agents or publishers of newspapers and magazines. To compile such a book every year, and keep all the facts up to date, is certainly a great triumph, for it names 23,726 publications, gives their circulation, and also the statistics of every State, town, and village in the country. It is a monument of patience and perseverance.

## TO PURCHASERS OF VEHICLES.

The Elkhart Carriage and Harness Mfg., Co., of Elkhart, Indiana, have been advertising their wares in GLEANINGS for many years, and we have yet to hear one single complaint of their treatment of customers, though they must have sold thousands of dollars' worth of goods to our readers. We think this is about the best testimonial any firm could receive, because if there was any dissatisfaction we would hear of it sooner or later. For more than a third of a century they have been selling vehicles and harness on the mail-order plan. They commenced in a humble way, and now possess an immense factory where they turn out carriages and buggies by the wholesale. In addition they make a large quantity of harness. By means of their fine catalog of 250 pages they convey to the mind of the would-be customer a knowledge of what they have to sell as well as any salesman could, and probably better, for a book can be referred to as often as one chooses to use it; and the pictures and descriptions being truthful and accurate, there is no need to go further. If you wish to see a copy of this handsome catalog, just send a request for it and it will be forthcoming. It is reasonable to suppose that a firm which has no traveling salesmen, agents, jobbers, wholesalers, or retailers can sell cheaper than those who do. In towns and cities storage alone adds greatly to the cost of a vehicle. This can be saved. Please note the address, The Elkhart Carriage and Harness Mfg. Co., Elkhart, Indiana.

## Extracted Honey Wanted

We are always in the market.

If you have any to sell, mail small average sample to

**NATIONAL  
BISCUIT COMPANY**

Purchasing Department,  
Washington Blvd. & Morgan St.  
CHICAGO, ILL.

## HONEY WANTED.

Wanted to contract for 20,000 lbs. comb honey in shallow extracting-frames 5% inches deep.

Requirements: Honey to be produced on full sheets of extra-thin super foundation, in shallow extracting-frames, not wired.

Grade: Same as first three grades in GLEANINGS grading-rules—Fancy, A No. 1, and No. 1 (all included as one grade).

Quality: Honey must be produced from clover, bass-wood, or raspberry.

Combs must be even and of uniform thickness—not over one inch.

Will furnish frames, shipping-cases, and carriers for re-shipping the honey.

Bee-keepers in Michigan or Ohio interested in this proposition, write, stating approximate number of frames you can furnish, and price wanted for the honey per pound, *net weight*, F. O. B. Medina.

Address

HONEY BUYER,

c-o GLEANINGS IN BEE CULTURE,  
Medina, Ohio.

WE WILL BUY AND SELL

## HONEY

of the different grades and kinds.

If you have any to dispose of, or if you intend to buy, correspond with us.

We are always in the market for WAX at highest market prices.

### THE TRADE IN BEES AND QUEENS.

We would respectfully call the attention of many of our readers who are obliged to purchase bees and queens to the fact that now is the time to order if you wish to avoid disappointment. By delaying the matter till later, when the queen-breeders are immersed to the head in business, you run the risk of being kept waiting till the season is almost over. Besides, the breeder is not sure what to do, whether to breed an extra number or let the matter take care of itself. It would be vastly better for the customer as well as the breeder if orders were sent some time in advance of actual requirement. This gives both parties to the transaction an opportunity to do business on a safe and satisfactory basis. The real season for breeding good queens in the North is quite short; hence the express need of a proper understanding beforehand. Usually with a little forethought all unpleasantness can be avoided.

### FOUNTAIN PENS.

We are very glad to say a word in season in favor of the pens made and sold by the Laughlin Pen Co., of Detroit, and now advertised elsewhere in this journal. In our opinion, any person needing a good pen can very safely order from them; for, in addition to a positive guarantee with each pen, they make a very liberal offer to return the money plus the postage on all pens returned as unsatisfactory for any reason whatever. It strikes us nobody could do more in a business transaction than that, and for this reason we allowed the Laughlin Manufacturing Co. all the space they wanted to advertise their wares in this journal. We have given their Red Gem ink-pencil a fair trial, and found it was all it was represented to be, and a little more for good measure. We imagine the other pens they advertise are equally satisfactory, and it is out of the common to offer 14-carat gold fountain pens at the price they name. There is now strong competition in the pen business; but it is evident to us that the Laughlin firm can hold its own against all competitors when a really good fountain pen is wanted.

### THE GUIDE TO NATURE.

Our friend Dr. Edward F. Bigelow has launched his new periodical, which he entitles *The Guide to Nature*, and it is well worthy of its title, for we have already perused two num-

bers, which sufficiently show the trend of the magazine. It deals entertainingly with all phases of nature in such way that the ordinary man or woman can fully comprehend what is meant. It is a scientific magazine for the plain people. In the May number there is an imaginary story of savages in the jungles of the Hoang Hoe—just the material boys like to read. As a matter of fact it relates to a trip through a fine public park in the city of Stamford, Ct., where the explorer (Dr. Bigelow) meets with all sorts of wild things and many adventures. There is a department for the camera and another for the microscope; still another for domesticated nature, so that all tastes are catered to. It fulfills a mission.

### HATS FOR BEE-KEEPERS.

Now is the time the bee-keeper is looking around for a soft comfortable straw hat on which to fasten a bee-veil. Such a hat has to withstand a good deal of rough usage such as the average summer headgear is not expected to stand. A hat which seems to fill the requirements is advertised in this issue by the Francis E. Lester Co., Mesilla Park, N. M. These hats are hand-made in Mexico, where the art of straw-hat making is well understood. They are so constructed that they fit almost any head, and being tough and durable, last a good while, even when roughly used. The bee-veil may be lightly tacked to the rim by a few stitches, and anybody may find this to be a very efficient and satisfactory mode of preventing bee-stings on any part of the head; and yet the whole outfit is quite light and, at the same time, durable.

### TOEPPERWEIN'S WORD CONTEST.

Mr. Udo Toepperwein has written us to the effect that there were far more contestants than he had any idea of, and it will take time to discover who are the winners. An expert has been engaged to go over the answers, but it will be more than a week before he can make his report. In the meantime he asks all interested to exercise patience. He had a deluge.

# LISTEN!

## DO YOU HEAR THOSE BEES WORKING?

Soon they will want room or will swarm.

Have you gotten your hives and supplies? If not, send your order at once. If you have The A. I. Root Co.'s catalog you can order from it. We sell their goods at their factory prices. We can fill your orders promptly now. Write for further information and our 40-page catalog.

# BEE KEEPING

will be a profitable industry this season.

Honey is high—short crop last year. The shortage of the honey crop for 1907 in the United States warrants bee-keepers to increase their colonies. About a half crop was produced, and in California, where the cheap honey comes from, only a quarter of the average crop was produced.

## Get Ready Now for More Honey

Let us send you our catalog. We are manufacturers and sell only our own make of bee-supplies. Minneapolis is the largest lumber-distributing point; the Mississippi river furnishes us power, and our organization and labor conditions are the best for economical production. Send us an estimate of your requirements and let us give you prices. We have a large stock of standard bee-supplies on hand. Dovedetailed Hives, Sections, Section-holders, Separators, Brood-frames, Comb Foundation, Smokers, Extractors, Shipping-cases, etc.

## TO THE BEE-KEEPERS of CANADA.

WE are pleased to say that we are able to offer, in Canada, goods manufactured by The A. I. Root Co. While we do not offer every thing listed in their catalog, we have selected such articles as we believe will best meet the wants of the Canadian bee-keepers.

The heavy duty and freight charges we have to pay make it impossible for us to sell in Canada at Root's prices. We have, however, made prices as low as possible, and in no case do we charge nearly as much extra as the amount of freight and duty we ourselves have to pay on the goods.

We would ask you, when comparing our prices with those of other dealers, to take into consideration the QUALITY. If you do so we feel satisfied that you will place your order with us. The splendid quality of the material sent out by The A. I. Root Co. has given "Root's Goods" a world-wide reputation. Remember, "The best is cheapest."

# Three Issues for 10 Cents

The question of requeening annually, or allowing the bees to do it when they get ready, is of much importance, and I think that

## THE BEST ARGUMENT

yet in favor of the former is put up by S. D. Chapman in the *Bee-keepers' Review* for March—and then he shows how to do it at a cost of only five cents per colony for labor.

Many bee-keepers think it necessary to

## OPEN EVERY HIVE

in the apiary in order to ascertain the condition of the colonies; but it is astonishing to note the number of things that a veteran can decide without ever opening a hive; and there is certainly some interesting reading in an article on this subject by A. E. Burdick, in the April *Review*, entitled: Outside Indications of Internal Conditions.

Probably no queen-breeder in this country has had more experience in the production of a

**W. Z. Hutchinson,**

## HIGH GRADE OF QUEENS

in large quantities than has Mr. J. P. Moore, of Morgan, Ky.; and he tells in the May *Review* "How to Rear the Best Queens at the Lowest Cost." I think it the best article on queen-rearing that I ever read.

A man's success sometimes turns upon the kind of honey that he produces—that is, whether comb or extracted.

## THERE ARE REASONS

why you should give one kind the preference. If you are uncertain about it, read the article by R. L. Taylor, in the May *Review*. Its title is "Comparative Advantages of Comb and Extracted Honey Production."

Send 10 cts. for the March, April, and May issues, and the ten cents may apply on any subscription sent in during the year.

## A SPECIAL OFFER

will also be sent, showing how you can get the *Review* for this year and next at a very low price.

**:: Flint, Michigan**

## And Still They Come

The following letter from one of our customers demonstrates in his own words the satisfaction our customers receive. Remember this is only one of the many thousands we receive.

Griggs Bros., Toledo, O.:—I received the hives and supplies to-day, which is the quickest I ever got goods after ordering. They must have come over in the Knabenshue's airship. They certainly are in fine shape—utterly impossible for any thing to have got lost.

Your shipping-clerk had them packed to perfection.

Respectfully, HUGH RICHARDSON,  
Wood Co., O.

We should be pleased to list you as one of our customers if you are not one already. Bear in mind we handle ROOT'S GOODS exclusively, not the cheap shoddy stuff which others are trying to palm off under the pretense that it's "as good as ROOT'S." Try ROOT'S and you will be convinced. TOLEDO is the place to buy; we save our customers annually thousands of dollars in FREIGHT.

A complete line of Incubators and Poultry Supplies listed in our free catalog. Send for one.

Honey and Beeswax wanted in exchange for supplies.

## THE DANZENBAKER SMOKER

PAT. OCT. 3, '06, JUNE 4, '07

### GOLD MEDALS

St. Louis Exposition, 1904  
Jamestown Exposition, 1907

IS THE BEST,  
STRONGEST,  
COOLEST,  
CLEANEST,  
CHEAPEST,  
AND LARGEST  
SMOKER SOLD  
FOR A DOLLAR

The perforated side grate seen above holds a removable, metal, asbestos-backed fire shell, preventing burning the tin off the outer case, and deflects the air at right angles, preventing back draft to the valveless bellows. The air, passing to the back and over the top, cools and expels the smoke, fanning the burning fuel at top or side till all consumed, giving cool smoke for hours from one filling. It can't clog. No top-heavy cap to choke with soot: no valve to fail; no holes shedding sparks or hot ashes.

Four years' sales prove its success beyond a doubt, expensive dies making it uniformly perfect as possible to devise. We confidently guarantee full satisfaction or refund the price.

Price, \$1.00; 3 for \$2.50; by mail, add 25c. each

Send address of yourself and Bee friends for 8-page leaflet on "Smoker," and facts about Bees and Queens, 80 pages, free.

NO. 7

## STRAY STRAWS

DR. C. C. MILLER

"EIGHT QUEENS in one box hive," page 562. That's a stunner. How was it done? Did the eight winter together?

A. I. ROOT, p. 587, seems to be a little skeptical about the "good old times when we were young." I arise to endorse him by saying that never was there a year with more fun to the acre since I began to have fun than this good year of our Lord 1908.

KOUMIS. One quart of new milk, one dessert-spoonful of honey, one teaspoonful of yeast. Make the milk just warm, add to it the yeast and honey, pour into a large jug, and pass from one jug to another for three or four times. Put each pint of koumis into a quart bottle, cork tightly, and keep in a warm room for 24 hours.—*Chicago Record-Herald*.

"SUGGESTIONS thankfully received" anent those several thousand pounds of honey candied in the combs, says New Mexico Chap, page 580. All right, here you are. Spread the combs flat on the ground where the sun won't melt them; and as the bees lick them dry, sprinkle them with water from a watering-can. But unless used for brood-rearing I fear the honey would soon be candied again.

THAT UNITED STATES analysis of honey, reviewed p. 549, surprised me in more than one way. It shows, as mentioned, that what is generally supposed to be honey from one kind of flower contains pollen of several kinds; also that alfalfa pollen was found in white-clover honey from States where alfalfa honey is supposed to be unknown. I had supposed that inversion of nectar took place only while in the honey-sac of the bees, but learned from that bulletin that inversion continues after the honey is sealed up in the comb.

B. D. HALL's plan of wintering two nuclei in one hive with a thin bee-tight division-board, p. 582, works all right. I have wintered many nuclei in that way. Looking under I could always see each nucleus clustered up against the division-board, the two forming a single cluster. It is well always to see that heavy frames of honey are up against the division-board, otherwise there is danger that the honey will be eaten away from the center, and one or both of the nuclei will have to move away from the center, losing the advantage of mutual heat.

MY SYMPATHY is with that New Mexico chap, p. 580, in the matter of "taking off honey in the afternoon so that the bees will not sting you, and

the neighbors." In this locality the forenoon is generally the better time to take off honey; but when one makes a business of bee-keeping he can't stop for any particular time of day, but must work "from early morn till dewy eve," and sometimes later. Often we have started to work at 4 o'clock, A. M., and once we finished the day's work at an out-apiary by finding and clipping a queen by moonlight.

YE EDITOR says, page 486, "But what is to interfere with the apiarist giving A an empty comb at the time he gives her a frame of young brood from B?" A very serious interference is the lack of additional bees to cover the additional comb. [Perhaps; but under the conditions named, if we understand it rightly, there should be a sufficient number of bees to cover the additional comb.—ED.]

ENDORING your instruction, Mr. Editor, page 584, not to remove the old queen till the new one is in, let me add that, for extra precaution, it is well to go a step further and not remove the old queen till one to three days *after* the new one is introduced. Put in the new queen, caged, with no chance for the bees to release her; one to three days later take the old queen out and let the bees at the candy. That gives the new queen the same advantage we have in the dual plan of introducing virgins in nuclei. [A good suggestion.—ED.]

E. H. SHATTUCK, page 581, I have some doubt that the dent in your queen had any thing to do with her supersedure. I have had several dented queens that lived long and happily. [If you will look up page 581 you will see that Mr. Shattuck said that the small dent appeared between the "wing-sockets." This shows that the injury in question was in the thorax, in the center of the back, and not on the abdomen of the queen. We have had a good many queens with dents in this portion of the anatomy; and these dents rarely if ever do any harm. Some of the best and most prolific queens we ever had carried a dent in their abdomens during their entire life; but a dent in the back between the wing-sockets would be a very different matter. Perhaps the dent you refer to was in the thorax; but we infer that you meant in the abdomen.—ED.]

WHEN BEES are placed on a new stand to form a nucleus, they will promptly desert their brood, according to what we are sometimes told. I have formed hundreds of nuclei, and have had very little trouble from desertion. There is an immense difference between queenless and queen-right bees. While bees taken directly from a laying queen are anxious to get back to their home, queenless bees will mostly stay where they are put. The strength of the nucleus also makes a difference. A very few bees seem lonesome, and

feel like hiking out. Three frames of brood with adhering bees taken from a colony that has been queenless two days or more will stay in satisfactory numbers, wherever put, without any imprisonment. If only two frames are taken, the entrance should be plugged with green leaves or grass, which may be removed in three or four days, or the bees may be allowed to dig their way out as the leaves dry. No danger of smothering in a full-sized hive.

D. M. MACDONALD objects to the limited sense in which we use the word "tested" when speaking of a "tested queen." I do not blame him. ["Tested" has come to mean, by common consent, unless otherwise modified by some adjective, a pure queen and nothing more; that is, pure Caucasian, pure Carniolan, pure Italian, etc. It takes about 30 days to test her for this purpose. A select tested queen means one that is of good size and color, fairly prolific, with good-looking pure bees. "Extra select tested" means that she is extra in the qualities named. "Breeding queens" takes in the next higher grade, and has reference to a queen that has been tested for queen daughters as well as bees that she can produce. A queen that will not produce a fairly uniform marking of queens, whose bees do not show some of the qualities of the bees of their grandmother, can not be used for a breeder. She may show up well herself; but it is what her daughters will do that determines her value to the queen-breeder and to the man who would buy her. Then the word "breeder" is further qualified by the phrase "select" and "extra select." Extra and extra select take in all the desirable qualities usually named for a good strain of honey-gathering bees.

THE ALEXANDER plan for weak colonies in the spring was a dead failure the first time I tried it. I put a very weak colony over a very strong one, with an excluder between, and within 15 minutes the lower bees were carrying out dead bees from above. Since then I have put a wire cloth between the two stories for the first three or four days, and it is an entire success. After removing the wire cloth I take ripe brood from below without bees and put above. The bees promptly come up, making the upper colony the stronger. Then when it is returned to its own stand it will be weakened by the loss of field bees, making the two colonies of equal strength. [A good many had trouble with the Alexander plan when they first tried it, and so did we. It is important to put the two lots of bees together with as little disturbance as possible. But in spite of any thing that can be done, bees, especially some strains, will be stirred up, and then there will be trouble. The only sure way of keeping them from fighting is to place a wire-cloth screen between the upper and lower stories for two or three days, as you suggest. At the end of that time it may be removed, when every thing will move along harmoniously. We therefore advise and recommend in our A B C of Bee Culture, where this method is given, the use of wire cloth for three or four days as a precaution.

The Alexander bees are a very gentle leather-colored strain, and, when handled by a man who knows how, the wire cloth may be omitted. But the average beginner—yes, we may say the aver-

age bee-keeper—will do well to use the screen.—ED.]

YE EDITOR figures, p. 557, that a queen-trap does not shut off much ventilation because the area of passage in the trap is greater than the area of the hive-entrance. I don't believe you are figuring on the right basis, Mr. Editor. One year I had combs melt down in hives because of a cornfield on one side and dense underbrush on the other, although the area of passage through the corn and underbrush was many thousand times greater than the area of the hive-entrance. Will not the trap close to the hive be as bad as the underbrush a rod away? [It can hardly be possible, doctor, that a cornfield on one side and underbrush on the other would so obstruct the entrance that the combs would melt down. Was there not some other untoward condition? As long as the sun does not strike directly on the hive, the bees, in the northern States at least, can make up for lack of circulation of air *around* the hive by an artificial circulation of their own *inside* of the hive to prevent melting down, providing the entrance be large enough. Of course, a perforated zinc or wire guard might cause some friction in air-currents; but as long as the passage-way is four times that of an ordinary entrance, we do not believe that the item of friction of the air in passing the bars or perforations would cut much of a figure. It never has with us, and we have had hives exposed to the heat of the sun. But if, on the other hand, we have too small an entrance on a hot day in a strong colony there is almost sure to be trouble.—ED.]

## EDITORIAL

---

THE National Irrigation Congress meets this year at Albuquerque, New Mexico. It is expected to be the most successful meeting yet held. More particulars later.

THERE will be a land-opening at Twin Falls, Idaho, on June 1, when 80,000 acres of irrigable land will be disposed of under the Carey act. Homesteads may be obtained by power of attorney.

IN the case of weak colonies we are not sure that the storm-doors were an unqualified success, although we believe they helped in the case of the strong ones. We will explain this matter a little more fully next fall, and will at that time be prepared to submit several models which we hope will overcome to some extent the defects of those already tried.

THE National Bee-keepers' Convention meets this year at Detroit, Oct. 13, 14, 15. Make a mental resolve to be there. Also, promise your wife that you will take her along. The opportunities are great for a real good time for every one. Besides, Detroit is central, and an admirable place for a convention. Probably you will take care of the bees with greater zest this summer if these hints are taken to heart.

Now is the time of all the year when the bee-keeper will need to put in his best efforts. There is an abundance of clover this year, and there is a chance of getting something providing he is up and doing.

MANY ignorant fruit-growers will be spraying their trees while in bloom. Our bee-keeping friends should wait upon these people, and in the most kindly manner show them their mistake from the standpoint of the fruit-grower as well as that of the bee-keeper. If you haven't any literature to hand them write us for it.

THE next session of the Farmers' National Congress will meet at Madison, Wisconsin, beginning Sept. 24. This will present a unique opportunity for some of our readers to hear men of national and international fame discuss the great farm problems of our time. It is a sort of institute of institutes.

#### OUR NEW FACE OF TYPE.

NOTICE that this issue is printed on a brand-new face of type. Our big editions, with an occasional double number, have been wearing out our old type very rapidly. It takes only a year now, with our big circulation, to wear out nearly 1500 lbs. of type on GLEANINGS alone.

#### \$4000 FOR 400 COLONIES OF BEES IN TEXAS.

WHILE conditions for a honey-flow in Southwest Texas have been somewhat discouraging of late, yet it is significant that there is enough confidence in the industry for one party to pay another one \$4000 for 400 colonies of bees. This price for so large a number, in spite of the discouraging conditions for the last two years in that portion of the country, shows a confidence in bee-keeping in the Lone Star State scarcely equaled anywhere else.

#### PROSPECTS FAVORABLE FOR THE EASTERN STATES.

JUDGING by the rush of orders that have come in, the prospects in most of the Eastern States for a honey-flow seem to be very good. While the spring has been somewhat backward, and even cold in many States, it has been by no means as unfavorable as a year ago, during which thousands of colonies all over the country were lost. There has been a large amount of rainfall; and if suitable weather comes on in June and July there is every prospect of there being a fair crop.

#### ANOTHER WORD TO THOSE WHOSE SUBSCRIPTION EXPIRES.

WE are rapidly taking out the names of those who are back on their subscriptions; for under the new ruling of the Department, as we have already stated, we are not allowed to continue any subscription except a short period after the time for which it is paid. It is important for those in arrears, who do not wish to lose any of the numbers, to renew at once, as we can not promise to supply any back numbers between the time of stopping the journal and the commencing of it again, although we will furnish as long as our supply lasts.

#### PARCELS-POST LEGISLATION DENIED BY THIS CONGRESS.

It is practically decided there will be no parcels-post legislation this session of Congress. The Postmaster-General has done his best to influence legislation along this line, but to no purpose. He has shown that a parcels post on rural routes would make rural free delivery self-sustaining. He estimates that there are nearly 40,000 rural routes, serving 15,000,000 people, which would, at the lowest calculation, average five packages each trip throughout the year. This would give an increased revenue of \$15,000,000, and that sum, it is estimated, would wipe out the present deficiency. But it is no use; the politicians are thoroughly alarmed—in fact, they are scared to mention the subject at all, as an election is near at hand. While this Congress didn't give us parcels post it will come—yes, is bound to come. Political bugaboos can not always keep back what is a great success in Europe.

W. K. M.

#### SOUTHERN CALIFORNIA SAGE CROP A FAILURE AND BEES STARVING TO DEATH.

THOUSANDS of colonies, owing to unfavorable conditions, in Southern California, are reported to be dying of sheer starvation. When the question is asked, "Why don't the bee-keepers feed?" the answer is that there is no honey crop in sight, and they feel that they can not draw on an already attenuated, or, worse yet, overdrawn bank account to buy sugar in sufficient quantities to keep the bees over until next February or March for a honey-flow that may or may not come. The policy with some, at least, seems to be to let the colonies starve except a comparatively small number; and when the next flow actually is in good prospect this number is increased. Whether it is cheaper to increase than to keep alive by feeding a large force of bees is a serious question.

In some portions of Southern California where there is irrigation there will be a crop as usual. It is the lack of rains on the mountainsides that can not be irrigated that plays havoc with the sages.

#### IDENTIFYING HONEY BY MEANS OF POLLEN-GRAINS AS SEEN UNDER THE MICROSCOPE.

THE following letter, received from W. J. Young, Assistant of the Chemical Laboratory of the Bureau of Chemistry, of the Department of Agriculture, Washington, D. C., will explain itself. Mr. Young, it will be remembered, was one of the authors of the United States Bulletin, No. 110, of the Department of Agriculture, a review of which we gave on page 549 of our last issue. His interest in this matter is certainly appreciated, and we feel sure our subscribers will be glad to respond by sending him samples. The letter is as follows:

Mr. Root:—I have been interested in the discussion of the color of heartsease honey in GLEANINGS for Dec. 15, 1907, p. 1504, and elsewhere, and believe that the case might be settled with comparative ease by a microscopical examination of the pollen along lines pointed out in Bulletin No. 110 of this Bureau. I am, therefore, writing to your contributors in order to obtain, if possible, samples of what they consider to be heartsease honey. Should any of your readers be in position to aid me in securing such samples I should be pleased to have them communicate with me about the matter.

W. J. YOUNG,

April 25.

Assistant Microchemical Laboratory

#### THE PREVENTION OF SWARMING IN RUNNING FOR EXTRACTED HONEY.

In this issue we have two quite notable articles, one by W. Z. Hutchinson and the other by E. D. Townsend, on the production of extracted honey, giving methods in connection therewith for the prevention of swarming. We tested modifications of these in our own yards some years ago, and we found them eminently successful. The drawing of the brood from the lower story, and putting it into another upper story, gives the queen more laying room and breaks up very largely the tendency to swarm, for the time being. Of course, the swarming problem is comparatively simple in the production of extracted honey; but there are some methods that are more satisfactory than others, and among the former may be named those advocated by the writers above.

#### THE APPALACHIAN FOREST RESERVE.

NOTHING will be done by the present Congress with regard to the above-named reserve, as proposed by its advocates. Judge J. J. Jenkins, chairman of the House Committee having the matter in charge, reported that, so far as he and his committee could see, to create such a reserve was not a function of the United States government unless it could be shown that it would have a beneficial effect on navigable rivers whose sources lie in the mountains intended to be reserved. This will hardly kill the project, because one of the objects of the proposed reserve is to protect the flow of the rivers by keeping back floods and letting down water during dry spells. It is the most gigantic enterprise ever proposed by any government, as it would eventually cost 1000 million dollars, and stretch for 1500 miles, from Maine to Georgia or Alabama. Nearly 1000 commercial organizations reported in its favor, and the general attitude of Congress is favorable; but it is too large an enterprise to be settled offhand. It would be a grand bee-keepers' reserve.

W. K. M.

#### SOUTHERN BEE CULTURE.

MR. J. J. WILDER, the aggressive and enterprising apiculturist of Cordele, Ga., has recently entered the lists of bee authors and publishers by the introduction of a new book on bees and bee-keeping with the title of "Southern Bee Culture," published by The A. I. Root Co. There was a distinct need of such a book, for in recent years we have had no work dealing specifically with bee-keeping as it is practiced in the great and beautiful southland we know as Dixie. We are of the opinion this new work will fill all requirements, as it is written by a Southern man of great experience and practical knowledge; besides, he has added, to his own observations, communications from well-known Southern bee-keepers, such as Mr. Louis H. Scholl, of Texas; Mrs. Mary L. Hawley, of Oklahoma; Messrs. Worthington and Smith, of Mississippi; Messrs. Crawford and Dawson, of Louisiana; Messrs. Bearden and Forehand, of Alabama; Messrs. Chatham and Simpson, of South Carolina; Mr. C. C. Ramsey, of North Carolina; Mr. T. S. Hall, of North Georgia, and Messrs. Hirshen and Tuck-

er, of Florida. In this way the book covers a wide field with accurate information as to the bee-keeping possibilities.

Over a great portion of this territory the bee-keeping resources are imperfectly developed or not at all. There are still far too many bee-keepers in the South who use "gums"—not hives. These have the merit of being cheap, but they get "cheap" results. Mr. Wilder addresses himself to this class, and the instruction he gives is plain and practical. He eschews all superfluities, and deals largely with the practical. His aim is, evidently, to advise the beginner; but many others will find the book readable and instructive—more particularly those who would like to move to a new location in the South.

The pages are about the size of these, and there are 150. The price is 50 cents in paper covers, which we think is reasonable, for the book is well printed on good paper, and fairly well supplied with suitable illustrations. W. K. M.

#### EXTRACTED-HONEY PACKAGES; PREVENTING LEAKAGE AROUND THE CAPS.

AT the last convention of the Northern Michigan Bee-keepers' Association, held at Mancelona, April 8 and 9, a very interesting discussion took place on the general subject of putting up extracted honey. In answer to the question, "How can honey be prevented from oozing out around the screw-caps of pint-cans?" the following plan was given:

Fill the cans with honey, and place them in water heated to 160°. While they are still hot, put on the caps and turn them down as far as possible, being careful meanwhile to have every thing level, so that the honey may not wet the rubbers. After the cans are cool, the caps may be turned down a little more; and if the rubbers during this time have been kept dry there will be no leakage.

In Northern Michigan, considerable honey is put up in tumblers, and there were several plans given for making the caps tight. One member advised brushing the insides of the caps with melted paraffine and then applying them to the tumblers which had meanwhile been filled and cooled. With this plan no paper is used.

Another used paper disks cut about half an inch larger in diameter than the top of the tumbler. These were dipped in hot paraffine, instantly applied to the tumblers, and crowded down over the tops with hot caps. Parchment paper was used. Ordinary paraffined paper would not do, since it must be wet with hot paraffine at the time it is put on.

Mr. C. F. Smith, of Sheboygan, uses no paraffine at all, and still has no leakage. He procures a special crinkled paper like that used as a lining for sugar-barrels, and the disks made of this are crowded on the tops of the tumblers under tightly fitting caps. With this plan, and, in fact, with any similar plan, it is important that the tumblers be uniform in size, so that there may be no variation in the fitting of the caps.

Corrugated paper should be used under and over the jars in the crate, and the cover of the crate should then press lightly on the corrugated paper in order to prevent any possible loosening of the caps during shipment.

### REQUEENING ALMOST AUTOMATICALLY.

The following, appearing in the *Bee-keepers' Review* for April, looks so feasible that we are glad to offer it to our readers:

Mr. J. H. Collins, of Bardwell, Kentucky, writes me of a plan he uses in requeening, whereby it is not even necessary to hunt up the old queen. Here is the plan:—

Prepare a super or upper story by boring two holes near its lower edge. Cover one hole with a piece of queen-excluding zinc, and fit into the other a tube, several inches long, made of wire cloth. A tube half an inch in diameter and six inches long is large enough. Lay a queen-excluder over the brood-nest of the hive that is to be requeened, set on the super prepared as just described, having the openings over the entrance to the lower hive, and put into the super two combs of brood. The bees from below will come up and cover the brood, when they should be cut off from the lower hive by putting a piece of wire cloth between the upper and lower hives. The warm air and odor from the lower hive can come up into the super, but the bees in the latter must use for an entrance the holes that were bored, one covered with queen-excluding metal, and the other furnished with a tube of wire cloth.

The next step is to furnish this super with either a ripe queen-cell or a virgin queen. When ready to mate, the queen will leave the hive by the way of the wire-cloth tube, but is almost certain not to find the outer opening upon her return, and to be attracted to the lower entrance by the crowd of bees passing out and in. The young queen is vigorous, slim, and spry, while the old queen is more feeble, slower, and clumsy from her load of eggs. The result is that the young queen comes off victorious.

### HIVES VS. METHODS FOR PREVENTING SWARMING.

PROBABLY no other subject related to bee-keeping has been so thoroughly discussed as has the swarming question, and yet something new is appearing all the while. By far the greatest proportion of the matter relative to the subject has to do with methods rather than fixtures; but for some reason, there is no one method that gives universal satisfaction for preventing swarming year after year. In view of this, Mr. Aspinwall has been working persistently for a long time to perfect his non-swarming hive, which, as most of our readers know, has been described in these columns. One extensive producer, however, in commenting on the Aspinwall hive in the *Bee-keepers' Review*, page 111, contends that he would not want it, even if it should prove to be all that the inventor now claims for it. He says:

From past writings from several sources, it is apparent that some of us know enough to put in practice very successful non-swarming methods, holding all of the bees together, if we wish, and I have no doubt that these methods require as little labor as is required in the management of the Aspinwall hive. Mr. Aspinwall must spread his brood-combs, insert slatted dummies, then "remove the outside comb of the strongest colonies at the end of two or three weeks of white-clover yield because solid with pollen."

A successful method can be applied to almost any hive, with any supers; while to stock our yards with hundreds of non-swarming hives and supers will mean the discarding of tens of thousands of dollars' worth of supplies, and the purchase of other supplies at a cost of at least double the cost of the old outfit.

I am entirely willing that the non-swarming hive be further improved and put before the people for trial in various localities; but I shall continue to search and study for better non-swarming methods, confident that I seek a better and more logical solution than do the seekers for the non-swarming hive.

### "CORN SYRUP" OBJECTIONABLE AS A SYNONYM FOR "GLUCOSE" ACCORDING TO THE MAINE EXPERIMENT STATION.

PERHAPS some of our readers are of the opinion that we are rather too hard on glucose as a food; but GLEANINGS is by no means alone; in fact, the class publications, which thoroughly understand the problem, are at one with us in condemning the recent glucose-corn-syrup decision made by Secretaries Strauss, Wilson, and Cortel-

you, sometimes known as the "kitchen cabinet." The *American Grocer*, representing the grocery trade, and the *Louisiana Planter*, representing the cane-syrup trade, are strong denouncers of the corn-syrup decision. It may be thought that these organs are unduly prejudiced; but here comes the report of the Maine Experiment Station. Note what it says:

#### ADULTERATED AND MISBRANDED MOLASSES.

Practically the only adulterant found was glucose. Most of the samples examined carried sulphurous acid. In practically every instance the glucose was added to improve the color and "body" of the molasses. In most cases the goods were correctly branded, although frequently the word "corn syrup" was used as a synonym for glucose. Corn syrup is objectionable as a synonym for glucose for many reasons, chief among which is that it is not a syrup as defined in the Maine food standards, and it is misleading, as the average consumer does not realize that glucose is meant by corn syrup.

W. K. M.

### SWEET CLOVER GETS ITS DUE.

*Wallace's Farmer*, published in Waterloo, Ia., is generally credited with being the very best authority among farm journals when clovers are up for discussion, so that any thing it has to say is worth reading and studying over. We recently had occasion to commend its position on the problem of sweet clover as a fodder-plant. Again we are privileged to quote another pronouncement in its favor by the same authority. What it says deserves careful consideration by all American bee-keepers. If your neighbors are prejudiced, reason with them, and endeavor to show them that sweet clover is nearly the equal of alfalfa for feeding, and yet it grows almost anywhere. Most writers seem to forget that sweet clover is admirably suited to sheep-feeding, and in the famous San Luis Valley, of Colorado, hogs are pastured on it, and finished off on peas, producing the finest pork known to this country. Also the finest lamb mutton is produced there. Here is what *Wallace's* says:

#### IS SWEET CLOVER A WEED OR A VALUABLE GRASS?

Farmers generally regard sweet clover, also known as *Melilotus alba* or Bokhara clover, as a weed—not a bad one, but unsightly, though fragrant.

In the drier sections where clover does not grow readily, this grass may be regarded as valuable. It is true that cattle do not eat it readily until accustomed to it; neither do most men like tomatoes at first, though they may become very fond of them afterward. We happen to know two or three men who use sweet clover for pasture right along, and have no complaint about their cattle not eating it. One of our correspondents in Eastern Iowa, writing with reference to the fields of Mr. Coverdale, who recommended it so highly in our columns last year, says:

"In regard to Mr. Coverdale's clover, I have been watching it very closely and believe there is something in it. His cattle went off this grass fast last fall, and sold in Chicago as high as three-months corn-fed cattle."

Sweet clover should not be considered a weed in sections where red clover does not do well and alfalfa is not practicable. There are sections in the South where sweet clover is probably the best clover they can grow. Whether it is a weed in the corn and grass States is evidently open to discussion. We do not recommend its growing where the farmer can grow either common red clover or alfalfa, because sweet clover makes a very coarse hay; and, besides, cattle have to be trained to eat it. Nevertheless, in view of the testimony of men who grow it, it must be considered an open question whether in this section it is a weed or a valuable grass.

W. K. M.

### A GLUT OF OFF GRADES OF COMB HONEY; PRICES FOR 1908.

AT the present time the markets are flooded with off grades and No. 2 comb honey, much of it candied. This is an unfortunate condition just now because the goods are seeking a buyer at greatly reduced prices, and these reduced prices have a tendency to depress the market on new

goods, fancy and No. 1. The general hard times, which will probably last for some months to come, will probably make prices on comb honey ease up somewhat; and we desire, therefore, to suggest that some producers raise less comb honey and more of extracted, because extracted always has a market, but at lower prices. Where one has white table honey, and can produce 90 per cent No. 1 and fancy comb honey he will have no trouble in selling it at good prices providing he markets *early*; but if, on the other hand, much of his crop is dark or off-flavored, he should produce extracted largely. Or if he has light honey, but is likely to have a sudden stoppage of the flow, leaving on his hands a large number of unfinished sections, he had better produce both comb and extracted, running more toward extracted as the season closes.

#### MORE IRRIGATION IN IDAHO, AND MORE ALFALFA COUNTRY TO BE OPENED UP.

WE have already alluded to the Carey law, by which public lands in the arid region are reclaimed by private enterprise under the immediate supervision of the government, which fixed the price the settler must pay, and, besides, inspects the dams and canals to insure stability. Generally speaking, lands obtained under the Carey law are actually as safe as Uncle Sam's own reclamation projects.

Reports from Idaho are to the effect that the Twin Falls region will soon have the largest tract of irrigated land in the United States, 1,550,000 acres. This will be accomplished by carrying the present canal on the south side across the Salmon River, thereby opening for settlement 800,000 acres now lying useless, but nevertheless rich land. The amounts in acres are as follows: Twin Falls, south side, 220,000; Twin Falls, north side, 200,000; Twin Falls, Salmon River, 150,000; Twin Falls pumping-plant, 50,000; Idaho Irrigating Co., 110,000; Glen Ferry Co., 20,000; total, 1,550,000 acres. In time this will sustain a population of 750,000 persons in peace and plenty. This means there will be a large expanse of good bee territory opened up to bee-keepers.

W. K. M.

#### THE PATENTABILITY OF AN APPARATUS OR DEVICE FOR MELTING CAPPINGS AS FAST AS THEY LEAVE THE UNCAPPING-KNIFE.

On page 560 of our last issue we discussed the patentability of the various devices for melting the cappings as fast as they fall from the uncapping-knife. It will be remembered that we stated that the patent of F. R. Beuhne, of Jan. 8, was not, in our opinion, broad in its claims, but confined to only one particular form of construction. We have since obtained the opinion of C. J. Williamson, a patent attorney and an expert on patented bee appliances, from Washington, D. C., who says the patent in question "is not a basic or broad one, but is of very limited scope. Each of his four claims is so narrow, indeed, that not one of them is infringed by either the Mercer apparatus described and illustrated in the article by your Mr. H. H. Root, pages 217, 218, GLEANINGS for Feb. 15, or by the Peterson apparatus illustrated and described in GLEANINGS for May 1, page 559." Continuing, he

says it is impossible for Mr. Beuhne or any one else to obtain any valid broad claims on his apparatus in view of certain other patents that have been granted to other parties, of prior dates.

When we wrote Mr. Williamson we told him it was our opinion that, while the claims of the Beuhne patent were narrow, the *specifications* were sufficiently explicit to bar any one else from securing any strong claims on an apparatus of a different construction. In reply to this he says, "Your Mr. E. R. Root is right in his view that the Beuhne patent would prevent any one else from obtaining a broad or basic claim on an apparatus for treating comb cappings unless such other persons could show that they completed their invention prior to July 10, 1907, the date of filing the application on which the Beuhne patent was issued."

For the present, at least, machines can be built on the lines of either the Mercer or the Peterson models by any one, and according to Mr. Williamson such builder can even go so far as to use the vertical cylinder for heating the uncapping-knife, shown in the Peterson drawing, page 559, last issue, providing it does not have an overflow pipe near the top and an emptying tap or faucet at the bottom.

But Mr. Peterson and Mr. Mercer have both filed applications, and they may be able to procure patents covering some detail of construction; but, according to the evidence before us, such detail would not be a vital part of the principle of melting the cappings as fast as they leave the knife, such cappings coming in contact with a hot plate or surface.

#### THE RUSSIAN GOVERNMENT EXPERIMENT STATION.

Mr. Abraham E. Titoff, formerly of Ioamosa, Cal., was a visitor to Medina for several days last month preparing for his return to Russia, where he will assume the position of Expert in Apiculture to the government of Kieff. The province of Kieff is admirably suited to bee culture, being known as the land of nightingales and cherry-blossoms. The climate is somewhat like that of Kentucky, probably. The city of Kieff is an educational, scientific, and literary center, being particularly famous for its great technical school, which is not surpassed by any other country. It also has a university and a number of colleges. Mr. Titoff's lines will, therefore, be cast in very pleasant places. He will travel through the state or province of Kieff, instructing the farmers in modern methods of keeping bees. During the five years he has spent in the United States he has perfected himself in the American methods of bee culture, and of course will do his best to instruct his Russian pupils in our methods. He intends to keep thoroughly well posted on all new developments in American bee-keeping. Mr. Titoff has a happy, friendly manner, so that we feel sure he will succeed in his new sphere of action.

Before leaving California Mr. Titoff disposed of his queen-rearing business to Mr. E. M. Graves, of Ohio, who will conduct it on the same good lines as formerly.

On his return to Russia, and when he gets the wheels of his office running smoothly, he expects to be able to breed a few Caucasian and Carniolan queens for export to this country. W. K. M.

# FANCIES AND FALLACIES

By J. E. CRANE

Those engravings of the buckling of foundation in sections, p. 152, are perfect. It tries my patience just to look at them.

L. E. Mercer's cartwheel arrangement of beehouse and apiary, p. 149, is novel and good, but not very economical of space. When hives are in straight rows, why not have open spaces in the rows or through the rows in a direct line from the house to any part of the yard?

On pages 158 and 159 Mr. Fr. Greiner makes some very interesting suggestions, and valuable ones as well. Let us plain honey-producers remember the use of a pin stuck in a stick for transferring those little soft crescent-shaped baby larvæ, which to me is the dread of artificial queen-rearing.

## A CHEAP AND SERVICEABLE FEEDER.

By the way, I used a new style of atmospheric feeder last fall. Being short of feeders I sent for 100 friction-top gallon cans. We had only to punch the cap full of holes, and we had 100 feeders holding about 10 lbs. of syrup, at a cost of 10 cts. apiece. When through feeding they can be cleaned, and used for a long time.

## LIQUEFYING CANDIED COMB HONEY.

The hot-air method of liquefying honey as described on page 145 is of considerable value. We have put in steam apparatus for this purpose the past season, and find it is easy to keep the temperature of our tank-room from 90 to 110 degrees. Honey kept there for a day or two is much more readily liquefied when placed in a water bath at 140.

## MAKE ALL THE MONEY YOU CAN.

"While you are making money at keeping bees, why not make all you can?" says Louis H. Scholl, page 206. Well, that depends. I have tried it a great many times, and never yet succeeded. It is a good deal like trying to get every hill of corn to yield as well as the best hill. I never could. Our seasons vary so that I almost always find at the close of a season I have made some mistake.

## ARTIFICIALLY REARED QUEENS.

Mr. Greiner, p. 158, fears that artificial queen-rearing will cause a deterioration of our bees. Guess not. Read and read again what Mr. Alexander says, p. 210. Let me quote: "As I look back I find that the seasons when we received our largest surplus have been, without a single exception, the ones following the year when we reared our queens from some special queen whose colony had given us an unusual amount of surplus the previous summer. It requires only four or five years of careful selection to make a great change in bees in their honey-gathering qual-

ities and in their disposition, until they seem like quite a different race of bees." This does not look like deterioration. Better tack this paragraph up over the door of the honey-house.

## ADULTERATION AND MISBRANDING.

W. K. Morrison, p. 202, says there is very little adulteration now. I believe he is correct; but while a single firm can put out, or bottle, 500,000 lbs. and upward, in one year, of Southern and amber California honey, and mark it all "pure clover honey," there will be room for some missionary work. [Give this firm's name over to the Secretary of Agriculture, Washington, D. C. This would stop such work.—ED.]

## HONEY AT HOTELS.

"Honey as an article of food at our leading hotels" is worth while to keep drumming up. I can bear witness to the good quality of the honey at the American House, Medina; and it is good advice, too, to supply them with only the best. And, say! another thing—when traveling ask your waiters at the tables for honey. It is amusing to see the vacant look on their faces as they retire and come back to inform you in a meek way that they have none.

## COMB-HONEY COLONIES SHORT OF STORES.

Stray Straws, p. 139, quotes Doolittle as saying that, in his locality, a colony which has stored comb honey is rarely short of stores for winter, but thinks it not true at Marengo with eight-frame hives. It is not true here, even with ten or twelve frame hives. There is a great difference whether we have only clover for surplus or clover, basswood, and buckwheat. Clover usually fails in July with the hive full of brood and scant stores.

## PROHIBITION ON PULLMAN CARS.

Stray Straw, p. 200, "Prohibition, nowadays, is all the while cropping out in new places and in new ways." Just so. Recently the Pullman Car Co. ordered all their cars in the United States to discontinue the sale of intoxicating liquors. Now if they will sell comb honey in all of their dining-cars, as they do in some of them, the bee-keepers of the country will be the last to complain. [Good suggestion. We may tell you on the sly that some bee-keepers are already furnishing the Pullman people comb honey, and they are buying lots of it.—ED.]

## DOOLITTLE'S SIMPLE PLAN OF REQUEENING.

In this same article, page 159, Mr. Greiner discusses requeening, and the best methods of introducing the young queens, none of which seem so simple and inexpensive, especially where extracted honey is produced, as that described on pages 45 and 111 of "Scientific Queen-rearing," by Doolittle, which is, briefly, this: Hatch a young queen in an upper story and shake her with the rest of the bees below, or in front of the entrance, when she will surely supersede the old queen. I think every year I will try this method on a larger scale; but when the time comes I find my hands so full of other things that I do not carry out my plans.

## BEE-STINGS FOR RHEUMATISM.

Your head is level when you say, Mr. Editor, p. 153, that you "have no faith in bee-stings as a cure for all forms of rheumatism, nor even for the same forms that afflict different individuals." Last spring, when our man Lewis came to help us, he complained bitterly of his swollen and inflamed wrists. He had been working in a damp pulp-mill. A few bee-stings applied gently to his painful wrists relieved him at once. On the other hand, I have been laid up for over five weeks this winter with rheumatism after receiving enough bee-stings to render me immune the rest of my life, I would suppose.

## VISITING BEE-KEEPERS.

"It pays the bee-keeper to go visiting occasionally. Whenever occasion offers, take a trip around to other bee-keepers, and a short stay with them may make you more enthusiastic when home again." He says, same page, and he never said a truer thing, "I never visited another bee-keeper without being benefited, so far as I remember. Even a shiftless bee-keeper may give you some points and set you to thinking." And now, friend Scholl, I wish to thank you for your efforts at exhibiting and introducing granulated honey. It is going to take a lot of "hot air" to introduce it and make every one understand it, but it must be done.

## THE LOSS IN FEEDING A THIN SYRUP.

The article by Allen Latham, p. 212, "Thick Syrup vs. Thin for Winter Feeding," is one of more than ordinary value, it seems to me. I have been especially interested in his estimate of the loss by feeding thin syrup in place of thick. I have no doubt in my own mind that his estimates are based on most carefully conducted experiments, and he knows whereof he affirms. He estimates there is a loss of nearly one-fourth by the activity of the bees in the amount of winter stores a given amount of sugar will give if fed thin or thick, to say nothing of the loss of vitality in the bees fed. I have fed a large amount of sugar syrup during the past 25 years. I began by feeding  $2\frac{1}{2}$  sugar to 1 of water; but after a time I dropped to 2 sugar to 1 water. If fed warm, bees will, as a rule, take it up quickly. Last fall I had one yard very short of stores, and required some 25 or 30 lbs. of thick syrup each, to last them until June. But this yard was some ten miles from home; and to save time and cost of hauling syrup so far I decided to take a ton of sugar to the yard and then get water near by and mix and feed thin syrup—half sugar and half water by weight. I did so, and finished feeding in three days, and thought it a success; but when I came to pack for winter I was astonished to see how light the hives were in stores, in this yard, and have been unable to account for it until these statements of Mr. Latham appeared. Had I fed all my bees in this way there would have been a loss of more than \$100 worth of sugar. I find no trouble, as a rule, in feeding sugar 2 to 1, if fed when warm. A single colony will sometimes take up 25 lbs. of syrup in 24 hours.

Later.—I felt anxious about those bees fed on thin syrup, and went up to the yard to look them over the fore part of March, and found 32 colo-

nies dead—yes, "dead as a door-nail," and every one was dead from starvation, and others were on short rations. Now, I have had to feed most of my colonies in the fall for the past 25 years, and this is the first time I have met with any serious loss from starvation, and also the first time I have ever fed thin syrup or cold syrup, and I can not help thinking there must have been quite a loss from warming and reducing so much thin syrup. It would even have required a considerable amount of fuel to warm and reduce 4500 lbs. of syrup (half water) to syrup one-fifth water. And this the bees had to do with the sugar syrup fed—rather expensive method. I had 136 colonies in this yard.

## BEE-KEEPING IN THE SOUTHWEST

BY LOUIS SCHOLL

The spring is at least a month early in most parts of the Southwest. The bees have been swarming since March 1, and all hives are just boiling over with bees.

The first honey-flow of 1908 opened about March 1. The main sources were Texas persimmon (*Diospyrus Texana*); round-flowered catclaw (*Acacia Raemneriana*), and several other early bloomers.

Wintering my bees in three shallow stories of the divisible-brood-chamber hive gives me a large brood-nest and rousing colonies early in the spring. The comb capacity is equal to 18 L. frames, and from 40 to 50 lbs. of honey is left to the bees in the fall.

The apiary making the largest average of surplus last season, and coming out strongest this spring, is made up of different combinations of hybrids from Holy Land stock. They are hustlers, but they hustle every thing at times. They are ferocious stingers. Now I am in a quandary—which is better, those stings or a few less pounds of honey?

To prevent swarming with the least amount of labor I cut up the brood-nest in the three shallow stories of the divisible-brood-chamber hives like this: The upper story is being gradually filled with honey from above, and the brood will be crowded out of it by the time the main honey-flow comes in April. The middle story is full of brood, while the lower one has only a portion of the upper part of its combs with brood. Swarming will be retarded until the honey-flow by simply placing the lower story, just mentioned, between the two filled stories, providing it is done immediately, *before the swarming fever is contracted*. In so doing we tear asunder the brood-nest by furnishing the story containing the frames having the empty cells for egg-laying. As soon as the honey-flow begins, all swarming ceases.

For the bee-keeper who does the right thing just before it is too late, swarm control is quite easy. Experience has taught me this again this

year with my fourteen apiaries and a most favorable spring for excessive swarming.

#### THOSE WIDE BOTTOM-BARS.

Wide bottom-bars are not only objectionable because they do not allow free examination of the combs from below, but frames with such are not as easily removed and replaced in the hive as those with narrow bottom-bars. In rapid handling, especially when the first comb is taken out, the wide bars cause the bees to be rolled over the combs of the next frames, and there is trouble—more so if the combs are not exactly straight. Then when the frames do not hang quite true they "stick together" below, and often two such wide bottom-bars can not be separated. How is it with you, Doctor Miller? I can't make 'em work here in Texas, and especially in big-scale bee-keeping.

#### BUCKWHEAT AS A HONEY-PLANT IN TEXAS.

A correspondent wishes to know about buckwheat in Texas for bees. It was given a trial for a period of three years at the Texas Agricultural and Mechanical College and Experiment Station, and as a honey-plant it has not proven of very much value, on account of the dry seasons that prevail in this State for the greater number of years. It thrives well in favorable seasons, and makes rapid growth, maturing to the flowering period in about thirty days. When the weather was favorable the blooming period extended over several weeks, and the bees worked on it industriously. By making successive plantings one month apart it was possible to obtain a succession of bloom for several months in early summer, before the heat was detrimental to its development. The first plantings were made in early April, the second in May, then in June and July. The later plantings generally succumbed to the drouth that usually sets in at that time.

The seed is planted best when drilled in rows just as cotton is planted here in the South. It was found that cultivating it in rows caused a better growth, and the buckwheat lasted longer. Sown broadcast it did not grow so luxuriantly, and soon seeded and died down.

As a honey-plant it did not prove a success, however. First, our seasons are not altogether favorable in too many years. Although it blooms profusely at times, it does not yield nectar. Then, second, the yield is not abundant enough to warrant planting for honey alone. Often the seed does not mature well enough to plant for that purpose. And, lastly, buckwheat honey is dark and of a rank flavor that would not find a place on our Texas markets. It is as dark and strong as some of our cane syrups or molasses, and therefore is not liked here.

#### WHEN TO REQUEEN.

It is not the best time to requeen in the spring of the year, for the reason that it is almost impossible to judge the right condition of a queen at that time, unless she has been marked the fall before. If a colony does not come up to requirements during the present season and the fall, and the same queen is behind the following spring, then she may be safely replaced. If she has not been kept track of the fall before, it is impossible

to know whether she is a poor one until later in the season. There are too many circumstances under which a queen is kept from doing her full duty in early spring. Her colony simply being weak does not necessarily prove that she is a poor queen. Conditions play a great part in this; the food supply, the condition and age of the bees, and other factors, add to this. Right in line with this is the following from L. B. Smith, of North Texas:

Did you ever notice what a difference there is in the same queen as to prolificness of good and poor years? For instance, I had several of my queens marked as "poor," and some marked as "very poor." These I expected to replace at an early date this spring. Now for the result: I have replaced but two or three of those queens, and I shall not replace the others, for they are proving the equal of any queen I ever had in my yards. Now, why this difference? It's bound to be the season. Last year was very poor for bees through the main breeding season (April and May). This year, as stated elsewhere, is at least a month ahead of the ordinary seasons, and we could not ask for a more favorable time so far for the bees; and should this favorable weather hold on I look for one of the largest honey crops Texas has ever furnished, owing to the fact that bees are all strong and well supplied with honey. I have never seen the various honey-plants of this part of the State in a more thrifty and promising condition.

A queen shows her failing best right after the honey-flow is over, and this is the best time to requeen here in the Southwest. It costs very little to do it, and, instead of having weak colonies to go into winter quarters, those with a fall-reared queen in the place of the old worn-out one, will have an extra lot of young worker bees—yes, a rousing colony in fine condition. Such a colony will store a little more fall honey than one having an old queen; and with this additional amount of stores and a great lot of young bees to last well into the next season, great results in the way of surplus honey can be secured, especially since the young queen will not swarm. A colony with an old queen is weaker, and is made up of older bees, since the queen ceased laying earlier.

## CONVERSATIONS WITH DOOLITTLE

#### LOCATION, SECTIONS, AND WIDE FRAMES.

"Say, Mr. Doolittle, do you know the source from which our first pollen comes in this locality—I mean the first which enables the bees to secure great loads of it, and all they want?"

"I think so—don't you?"

"Well, I just want to tell you what I found. There is a swampy piece of land about a mile southeast of my house, and that warm morning we had a few days ago started the bees out early, almost before sunrise. When I went out I thought they were robbing, as there was such a roar in the bee-yard, but upon looking I found the bees hustling in the hives with great loads of yellowish-green pollen, while the surging in and out of the hive was almost like what it is some mornings during basswood bloom. I took a circuit around the apiary to see where they were going, and found them headed for that swamp. After breakfast I started out; and when I got over there the elm-trees, which compose the timber in the swamp to a very great extent, were just roaring with bees; and where some of the branches came down low I could see the bees at work. I wish you could have been there and seen them."

"I know they looked beautiful to your eyes,

for I have seen the same things in years gone by during some warm morning the latter part of April or the first of May."

"Indeed they did look beautiful, and it was very reluctantly that I left them. But I want to say a few words about sections and section-holders. Mine annoy me. The section-holders have no top-bars—just ears to hold them up with. In putting in the sections the tops are spread outward; but when the holder full of sections is hung in the super the weight tends always to close the top, thus making the sections remain close together. This seems to make many of the sections diamond shape, so that, when I come to crate them for market, and they are pressed together in the crate, it brings them back square again, thus loosening the combs from two sides, setting the honey to running, and endangering a general breaking-down in shipping."

"The proneness of all but nailed sections to go diamond shape, or fall to pieces entirely, was what lead me to discard the whole business, and use only nailed sections—sections which do not depend upon the honey, comb, and propolis, which the bees put in and upon them to hold them from going to pieces during the shipment of the finished product."

"But don't you have trouble about breakage when shipping to New York or Philadelphia?"

"Very rarely; and when any are broken it is only one or two in a crate. A few years ago a shipment of my honey went to New York on the same car with a shipment of these sections which you are speaking of, both to the same commission man. Two sections in each of three crates out of my shipment were reported as broken, while the other shipment was so broken and smashed that it brought only a little over half the market price. In fact, nearly one-fourth of the honey leaked out before it arrived at the commission man's store."

"But don't you think there might be other reasons for this outcome?"

"Possibly but not probably, as the freight agent told me both were loaded with the same care. Let me give you another case: Two years ago I carted my honey to the railroad station in the auto; and as the springs were so easy I thought it not necessary to take any special pains to prevent its falling off. While on a smooth piece of road I was spinning along when I met a team, and, in turning out, one of the front wheels of the auto dropped into an old rut on the side of the road which was partly covered up so I did not notice it. This threw one of the top crates of honey off, it striking on the front wheel, then falling on the ground in such a way that the wheel struck the top and one corner of the crate, tearing the crate to pieces, and scattering the twenty sections all about over ten or twelve feet of the road. I stopped the auto, saying, as I got off, 'There goes \$3.50 worth of my best honey for my fool driving and fool loading, when, to my surprise, not a single section was broken. I collected the sections together; picked up the crate, and drove on. When I arrived at the railroad I borrowed a hammer and a few nails, remade the crate, and packed the sections in it. It went with the rest, sold for the same price, and the consumer never knew that his nice section honey had been nosing all over the road up here in

Onondaga Co. I would not take either the one-piece or the dovetailed sections as a gift if I could possibly buy the material for the nailed ones."

"But it takes lots of time to nail them."

"I know it takes a little longer to put them together; but this is done during the stormy days of winter; and after they are made they are a source of joy, and something which gives one a freedom from annoyance not possessed by any other section on the market."

"Well, I know that my experience with some of the sections has been very annoying, as well as with the section-holders."

"I think myself that your section-holders are somewhat to blame for your troubles. With properly made wide frames your sections would not go diamond shape, and the sections would be kept clean of propolis."

"With your wide frames, don't the bees varnish the tops of the sections all over with propolis?"

"No; I never could tolerate any thing which allowed the bees to have access to any part of the outside of the section, for where they so have, it takes double the time to clean our product ready for market—time that is the most valuable of any during the whole year, to say nothing of other objections. Wide frames properly made keep the sections nearly as clean and bright when removed, even on their edges, as when put on the hive; while the top and the whole outside looks as clean and new as they did when they first left the saw or sandpapering-machine."

#### CLIPPING QUEENS WITHOUT HANDLING THEM; CHANGING PLACES TO STOP ROBBERING.

Mr. Holtermann told us that we should propolize our fingers before catching a queen to clip her wings, and then change her from one hand into the other. I clip the wings of a queen with small crooked scissors while she is running up the comb. Several times I have found her in the act of looking into a cell, and off would come her wings, and she would look into the next one without knowing any thing had happened to her. I have practiced this plan ever since I started to clip wings of queens.

The plan I use to stop robbing is to change the places of the robbed and the robbing colonies. It works so well that I have never tried to improve upon it. The uproar is twice as bad after the change as before; but the robbing is stopped at once. It is amusing to see those robbers come rushing out with their loads of honey, to find out they had to take it back where they got it and turn around and defend the hive they had been robbing only a moment before. I have followed this plan ever since with good success. ISAAC BALMER.

Burlington, Ont.

[Both plans here spoken of have been mentioned before. Clipping a queen while on the comb was described by Friedman Greiner first in these columns, and then in the A B C and X Y Z of Bee Culture. The scheme of exchanging places of the robbing and robbed colony was described by A. I. Root in the first editions of the above-mentioned work. But even if these ideas are old they are good.—Ed.]

# GENERAL CORRESPONDENCE

## COMB AND EXTRACTED HONEY PRODUCED IN THE SAME SUPER PER A LA TOWNSEND.

### A Modification of the Split-section Plan.

BY R. R. FOSLER.

I wish to make a few remarks on articles which have appeared in GLEANINGS.

In Fig. 1 are several sections of bait combs partially drawn out from foundation put in by the Hand method in split sections. As you will notice, the foundation does not extend down to the lower end, as the foundation used was only  $3\frac{3}{4}$  in. wide instead of 5. I am in favor of this method in several ways: first, the combs are fastened to the sections better than in any way I have tried before. The few sections that I experimented with were not put in wide frames with top-bars as Mr. H. advises, but in common section-holders with simply the bottom and the ends. In this way the bees gnaw the edge of the foundation that projects through the wood at the top of the section, leaving it somewhat below the surface of the wood. In this crack the bees deposit small quantities of propolis, completely hiding the wax. After the sections are taken out and scraped it is almost

impossible to tell that there ever was any foundation there. The only objection I can see to this method is the buckling. These sections that I was experimenting with buckled slightly, but the photo does not show it.

Fig. 2 shows some finished sections with top and bottom starters. These are not filled out quite as perfectly as they might be, but were taken off as soon as capped over, which accounts for that. These were obtained by the plan of producing both comb and extracted honey in the same super, which Mr. Townsend described on page 776, June 1, last year. I consider this the best article that has appeared in GLEANINGS for some time. I tried the matter thoroughly, and am convinced that I have tried nothing better.

FIG. 1.—SPLIT SECTIONS CONTAINING FOUNDATION PARTLY DRAWN.

I also tried this on weak colonies that were not strong enough to work in comb-honey supers without the extracting-combs for baits. Shortly after this super was put on, the bees were found working on the extracting-combs at

the side of the super, and then when work was started in the sections it was started at each side instead of at the center; and, as a result, they were nearly all finished at the same time.

Milford, Neb.

FIG. 2.—HONEY PRODUCED IN A SUPER WITH EXTRACTING-COMBS AT THE SIDES.

This honey was removed as soon as capped, which accounts for the fact that the sections were not filled clear to the sides.

[The plan of producing comb and extracted honey in the same super, we are sure is all right, as we have tried something very similar. In the case of colonies slow about going into the supers, it is especially good.

We are not sure but that section-holder may be better

MEMBERS OF THE SOUTH IDAHO AND EAST OREGON BEE-KEEPERS' ASSOCIATION.

for split sections, in that they eliminate partially one objection—namely, the unfinished and man made look of the foundation projecting up through the wood at the top of the section. Has any one else any experience to offer on this point?—Ed.]

### **SOUTH IDAHO AND EAST OREGON BEE-KEEPERS' ASSOCIATION.**

#### **The Problem of Educating the Farmers Concerning the Proper Time for Cutting Alfalfa.**

BY A. E. GIPSON.

The South Idaho and East Oregon Bee-keepers' Association was organized four years ago at Parma, Ida., and is composed of representative bee-keepers of the sections of the two States named. The objects of the association are to bring about a coöperation among the honey-producers in all matters pertaining to that industry, and especially in buying supplies and in marketing the products of the apiaries.

In view of the high quality of the honey of this region, members of the association are coming to realize more fully each year the importance of placing it on the market in the best possible shape and so the matter of marketing is receiving a good deal of attention. This fact was shown at the last annual meeting of the organization, when the discussion of this subject was given so much prominence.

The great strides that are being made in irrigation enterprise in Southern Idaho, by means of which hundreds of thousands of acres of fertile land are being opened up, with alfalfa as a leader in crop rotation, reflects the future of bee-keep-

ing here. This great forage-plant is the main reliance of the honey-gatherers, and bee-men are directing their efforts toward securing as long a blooming season as possible for the benefit of the little workers. To this end they are trying to educate the farmers up to the point of not cutting the alfalfa crop too soon after it begins to bloom. The contention is that it is not only better for the bees, but for the nutritive value of the plant as a stock ration, to permit a pretty full blossoming before each cutting is made.

Fortunately the association has a membership composed largely of men of wide experience in the apiary. Some of them, furthermore, have national reputations.

E. F. Atwater, for example, is not only a successful man as a commercial bee-keeper, but is widely known as a writer and expert on matters pertaining to the industry.

G. J. Yoder is another careful and exceedingly well-informed man, and likewise a veteran in the business. Both of these men are known to many readers of GLEANINGS by reason of their demonstrations and valuable observations.

Other prominent members are F. A. Powers, F. R. Fouch, J. E. Lyon, Will Pennington, Ben Paine, H. C. Dudley, A. I. McClanahan, R. D. Bradshaw, T. A. Waale, John A. West, and Mrs. A. J. Mitchell. These, and others who could be named, are making local history for the bee industry that must count in the development of that industry in all this region of country.

The last annual meeting was well attended, and was of exceptional interest. The *Gem State Rural* says that from 3500 to 4000 colonies of bees were represented, and that the Boise Valley, Ida., alone marketed about seven cars of honey during the year 1907.

A committee was appointed, consisting of E.

F. Atwater, F. R. Fouch, R. H. Bradshaw, and Will Pennington to look up markets and suggest prices for the present year's crop.

The officers elected for the ensuing year were, J. E. Lyon, President, Boise; Ben Paine, Vice-President, Roswell; E. F. Atwater, Secretary and Treasurer, Meridian; F. A. Powers, Parma; R. A. Bradshaw, Payette. Caldwell, Idaho.

## A PROMISING YOUNG HELPER IN THE APIARY.

BY C. RANEY.

The engraving shows my niece, who is my only help in handling bees. Though but nine years old, she seems to have the bees charmed in some way, for she uses neither veil nor gloves, and never gets stung. The two hives in the picture belong to her. They were in fine shape for winter, weighing 200 lbs. each. Both were swarms hived last June. We took 75 finished sections from them last season.

Our principal honey crop in middle Tennessee is from the white and sweet clover.

Petersburg, Tenn.

## BEESWAX IN THE ARTS.

### Sulphuric Acid Makes Wax Unfit for Certain Manufacturing Purposes.

BY J. L. BYER.

The average bee-keeper has a very faint conception as to the various uses to which pure beeswax is put at the present time. As a matter of fact, the use of beeswax in the different manufacturing industries is increasing very fast; and if this were not the case it is quite certain that the price of this important product of the hive would be much lower than at present, which price, by the way, is none too high to say the least. During the last eight years I have marketed something over 3000 lbs. of beeswax, and yet it was only this winter that I found the various uses to which the wax is put, of which I previously had had no idea. Some time in December the manufacturers of a certain line of paper wrote me saying that my name had been given them as one likely to supply them with pure beeswax, and they asked me to quote prices and send sample for trial. In reply I stated that we had such confidence that our wax would prove satisfactory that we would forward 100 pounds; and if it did not prove to be satisfactory they could return it at our expense. They were told that the wax was rendered from old combs, was free of dirt, but only ordinary in color. Incidentally, I stated that, by remelting and clarifying with sulphuric

acid, the color would be improved; but I would not recommend this treatment, as I considered it a waste of time, and there was also a danger of overheating, and possibly destroying more or less the ductility of the wax.

On receipt of my letter they wrote me saying that, if any sulphuric acid had been used in rendering my wax, it would positively be useless for me to send even a sample. They were emphatic in the matter, and it was of the *greatest importance* to them to be certain that not the slightest trace of acid be present in any beeswax they purchased. In the end a five-pound cake was sent as a sample, and in the course of ten days a substantial order was received. Only a few days ago the manager of the factory told me that the wax gave entire satisfaction. However, the attitude of this firm

WINNIE C. MUSE, A YOUNG HELPER IN THE APIARY WHO USES NEITHER VEIL NOR GLOVES.

led me to do some investigating, and I find that a large number of dealers and manufacturers are under the impression that, for certain uses, the addition of sulphuric acid in rendering wax is harmful to the finished product. Whether this claim is well founded or not is not for me to say; but one fact was undisputably brought out by my inquiries, and that is, for *some* reason a large quantity of beeswax is being put on the market

D. DANIELSEN AND FAMILY, OF BRUSH, COL.

Mr. Danielson writes that his family consumes 60 lbs. of extracted honey every month—720 lbs. a year, on the average. This picture is not a poor testimonial as to the food value of honey.

that is entirely useless for certain manufacturing purposes. As intimated, rightly or wrongly, quite a number are putting the blame on sulphuric acid, and it is up to the bee-keepers to find out if their claim is correct or not.

Of course, it is generally assumed that *all* the sulphuric acid settles with the water at the bottom of the cakes of wax; but that such is not the case was fully proven to the writer and some others by a little incident that occurred last summer. A friend bought a lot of beautiful wax that had been clarified with sulphuric acid. The wax was remelted and run into tart-tins, and the small cakes were sold at fairs. These tins, after the wax was taken out, were covered with a greasy coating, and my friend was telling me only a few days ago that, up to the present, they had found no way of cleaning that coating from the tins. No doubt that, in this case, an excess of the acid had been used; but the case serves as an illustration as to what might happen any time if no exact formula was observed.

The manager of one of the departments of a manufacturing firm in New York State told me that they use thousands of pounds of beeswax, and at present know of no substitute to take its place. They had experienced considerable annoyance and loss by getting a lot of wax that would not work right, and now they would buy only after having found the sample satisfactory, and following shipments had to be guaranteed the same as sample.

This man was inclined to think that some of the wax was overheated in modern presses used, and the ductility, or (as he expressed it) the "life" was taken out of it. At least one extensive dealer in painters' and artists' supplies in the city of Toronto stipulates in all his contracts for wax that no sulphuric acid be used in the rendering of the same.

In submitting these statements it is not my intention to raise a false alarm; but to my mind the question is a very important one, and it seems to me that the opinions of the dealers and manufacturers are entitled to some consideration. That, as before stated, a lot of unsatisfactory wax is being put on the market, there is no question, but to decide just what is the cause of this state of affairs is another proposition. That a number of our best bee-keepers use the sulphuric acid does not necessarily prove the wisdom of that course. In all the wax I have rendered, only once did I use the acid, and yet I have never had a single complaint from those who have bought my wax. That the acid does not injure the wax for foundation purposes is self-evident from the fact: that thousands of pounds of such wax is used annually for that purpose. But in the making of foundation the wax undergoes different processes than is the case in other uses to which the beeswax is put.

Would it not be wise for the bee-keeper to dispense with sulphuric acid? then if the foundation-maker wishes or finds it necessary to add the acid, let him do so.

It is a subject I should like to see made the object of scientific research, so that we may definitely know the cause of so much inferior wax being produced. We may rest assured that, if the manufacturers continue to get much of this poor wax, science and invention will speedily come to the rescue, and we shall find our product supplanted by something else.

Mt. Joy, Ontario, Can.

## EXTENSIVE HONEY-CONSUMERS IN COLORADO.

### Honey from Alfalfa.

BY DANIEL DANIELSEN.

We have just had a picture of our family taken. You see we thrive well on honey and other good things. We consume 60 lbs. of extracted alfalfa honey every month in the year, besides a little comb honey. I began bee-keeping in 1891 in South Dakota; moved to Colorado in 1902, and have now about 130 colonies. Bees wintered well so far; but the trouble here is in the spring. There is no nectar for the bees until alfalfa comes. I wish there were some plant that would yield honey in May.

Brush, Col., Jan. 31, 1908.

## BEE-KEEPING IN TEXAS.

### Battling Against Ants, and Competing with the Mexican Strained Honey; [Some of the Sources of Honey.

BY S. M. CAMPBELL.

Bees in this part of the country make a little honey nearly the year round. Mesquite is the main honey-plant, and it generally blooms twice a year. The first crop of mesquite blooms in March; then these blossoms are shed, and in June the main crop comes; and, unless there is a big rain, it will last about four weeks. The ebony blooms several times a year (every time it rains), but it stays in bloom only three or four days at a time. During this time, however, it looks like

a bank of snow. The honey has an amber color and a very good flavor.

Tanassa blooms after every rain, but lasts only a few days each time; the blossom is like button-willow, but is not half as large.

The catclaw makes a very white honey, with a fine flavor. The huajilla (or guajilla, as some prefer to spell it) has a bunch of round ball-like blossoms, and, like button-willow, makes a white honey and fine flavor.

What this country lacks is moisture. Long intervals sometimes occur from one rain to another. About fifteen years ago it did not rain for eighteen months enough to wet a man in his shirtsleeves. All the creeks and lakes went dry except the Rio Grande River.

The photograph of my apiary does not show all the hives. The yard contains ninety-six hives in two long rows facing the east. The trees are of several different kinds. The one nearest the cactus is mesquite. The others, named in order, are ebony, nocaway, ebony, and nocaway. The hives are shaded all the way along by these trees. At the lower end, not shown, a hackberry-tree has 25 hives under it.

The bees are half Mexican and half Italian. I had a very fine Italian queen—the finest I ever owned. Her daughters were mated to black Mexican drones. These are said to be very cross, but my bees are the gentlest I ever worked with.

The reason the hives are set upon the long benches is on account of the ants, which are very numerous in the Southwest. There are several different kinds. The worst of them all is a little sugar-ant. I managed to kill them by using 16 gallons of kerosene. I would find their nest and dig a hole about the size of a common washpan, and pour in about a quart of kerosene. That would be the end of that nest. Sometimes it would take about five gallons to destroy all of the nests.

I worked up a nice honey trade in Brownsville, although it was a Mexican town. The people had been buying honey from the Mexicans for 50 cents a gallon, squeezed out by hand, including, of course, the bee-bread and young bees. The package used mostly was beer-bottles; and when the honey had set a while the neck of the

bottle would be full of bee bread and scum that would rise to the top. When I began selling my honey I put it up in glass Mason jars, from a pint to half a gallon, with a nice label on it. When I first went to the houses to sell the honey the people would ask the price, and I would tell them. Then they would say they could get honey from the Mexicans cheaper. But I nearly always made a sale before I left, for I told them how the Mexicans squeezed out the honey by hand, and explained the difference. It wasn't long before I could sell honey by the 60-lb. can to customers who began buying by the half-gallon.

Taft, Texas.

## A GOOD SURPLUS FROM A WEAK COLONY.

### Some Well-filled Frames.

BY WELCH BIBBEE.

Here is a picture of three Danzenbaker frames of honey taken off July 2, 1907. These are the nearest perfect of any that I have ever seen. They were produced by a colony that I thought was almost worthless—in fact, the hive-body was almost rotten, and I had intended to transfer the bees to a Danzenbaker hive; but the spring was so cold and backward that I just took the lid off the old hive and set the Danzenbaker hive on top, and thought that, as soon as they showed signs of being strong enough to transfer, I would put them in the new hive. Probably I did not watch them closely enough, for on July 2 I found that the ten frames were full, with brood in three frames. I took out five frames and put empty ones in their places; and as the colony was doing so well I put a super of 32 sections on

the old hive, and this Danzenbaker body on top of the sections. On the 13th I found the sections full and capped nicely, so you see the bees got busy. The flow of honey from July 1 to 15 was the largest I remember, and it was all from white clover.

Cottageville, W. Va., Aug. 12, 1907.

## A PRIZE BEE AND HONEY EXHIBIT AT THE VIRGINIA STATE FAIR.

### An Engineer and Bee-keeper.

BY J. S. YODER.

My exhibit of honey at the Virginia State Fair is shown in the engraving. I had four premium cards attached—one for best display of bees; one for best display of honey; one for best display of comb honey; one for best display of extracted honey. I feel proud of my first exhibit, as this is my third year with bees. I started with four hives of bees in eight-frame Dovetailed hives, and now have forty colonies in good condition.

Roanoke, Va., Feb. 12, 1908.

## A BEE-SHED FOR SHADE.

BY W. O. STEVENS.

The bee-shed in the picture was built simply for the purpose of keeping off the sun and rain, as I winter my bees in the cellar. They are taken from the cellar about the first or middle of April, and they usually begin to gather pollen about the middle of the month from willow and poplar.

I have sold all of the honey I have been able to produce, for 25 cts. per lb., in the villages near by, both extracted and comb. Bee-keeping is not carried on around here to any great extent.

South Paris, Maine.

## CUTTING BEE-TREES IN WINTER.

BY E. L. MINER.

The engraving shows a large red-oak bee-tree, measuring 17 ft. in circumference, which was cut Jan. 7, 1908, in Wayne, Ashtabula Co., O. A

A BEE-TREE 17 FEET IN CIRCUMFERENCE CUT IN  
MID-WINTER.

large swarm of three-banded Italians was captured, although the thermometer stood at 15° above zero, and it was snowing at the time.

There was no brood at all in the combs, and only about 10 lbs. of honey, all basswood, although neighbors say bees had lived in the tree for ten years or more.

I did not transfer the combs to a hive, but brushed the bees off the combs into a box prepared with cushions in advance. The bees were surrounded with dry rotten wood, and did not get chilled in transferring, as we took them out of the tree by the handfuls.

I had two hives containing large swarms in double brood-chambers, with lots of honey in the combs; and on returning home I transferred the bees from box to the lower

## EXTRACTED-HONEY PRODUCTION.

**The Locality and Methods Whereby Large Quantities of a Superior Article may be Secured in a Leisurely Fashion at a Low Cost; How to Control Swarming with a Minimum of Labor.**

BY W. Z. HUTCHINSON.

*Continued from last issue.*

[The second installment of this series is particularly seasonable and valuable, and we hope every extracted-honey producer will give it a careful reading. The scheme of having combs enough for the season, and extract *after* the honey-flow at our leisure, while not new is attractive, because it enables one to control swarming, and at the same time perform all the labor himself. When one considers that hired help is often wasteful and incompetent, and good help hard and sometimes impossible to get (worse yet, the cost of the help will, not infrequently, *absorb all the profit*), this plan looks good, to say the least. The whole thing is told so simply and clearly that any one can take it in easily.—ED.]

I would not advise any one to pull up stakes, leave his present location, and move to Northern Michigan without first going there in person, and investigating. To go there and establish a home and an apiary, or a series of them, will require a

lot of enthusiasm and grit, patience and perseverance, and time and money. If I had not had a fair stock of the first two I would never have attempted it.

However, I am happy to say that the success of my plan is not dependent upon a location in the raspberry region. It will work equally well in a clover region, but the clover is much more uncertain—likely to winter-kill, or the nectar secretion may be wiped out by drouth, rain, or cold weather.

THE PLAN IN A NUTSHELL; HOW ONE MAN CAN LOOK AFTER FIVE OR SIX APIARIES, EVEN DURING THE HONEY-FLOW.

I will first briefly outline the plan; then, as I go back and give details, the reader can the more readily see the "reasons why." In the first place there must be an abundance of empty combs and supers—enough to hold all of a possible crop—so that the bee-keeper can put on supers of comb at any time with no hesitancy—just as though the supply were limitless. Of course, these combs and supers cost something; but they have to be bought only once, so that their real cost is only the interest on the money. There is no attempt whatever to extract the honey during the harvest. All of this hustle and bustle and hurry and worry to extract in time to give the bees room during the harvest is done away with. If a colony or a whole apiary needs more room, simply give more supers of comb. This is a quick operation. One

man could look after five or six apiaries, even during the honey-flow, if all he had to do was to put on supers when they were needed, while one apiary would keep him busy if he had to extract the honey to give the bees room. If the hives, or some of them, become piled up too high, it is an easy matter to remove some of the top supers by the use of bee-escapes, and store the supers of honey in the bee-cellar—there is no need to extract at the time of removal unless there is plenty of time for doing the work.

After the harvest is over, comes the work of extracting; but there is no hurry about it; there are probably two months in which to do the work. The honey is all on the hives unless some of it has been removed, as suggested, when that which has been removed should be extracted first. That which is on the hives is not only safe but daily improving in quality. Without the invention of the bee-escape this plan would not be feasible. It is not practical to remove honey and brush off the bees after the close of the harvest; but by the proper use of the bee-escape the whole crop can be taken off with no commotion, no stinging, no robbing, and safely landed in the honey-house without a bee in the yard fairly realizing what has been taking place.

The bee-escape is an important link in this chain; but there is another one equally important, and that is, the use of artificial heat in warming the honey so that it can be extracted when taken off late in the season by the use of escapes. Honey left on the hive all the season becomes well ripened and thick, and the cool weather makes it still thicker and stiffer; and it would be difficult to extract if the work were done immediately upon its removal. If taken off in large quantities by the use of escapes it would be simply impossible to extract it without warming it up. When it is properly warmed up to the right degree it can be extracted more readily, easier, and cleaner than when taken right from the bees in hot weather. As such honey is thoroughly ripened, there is no necessity for any settling-tanks; the honey can be run right from the strainer into the cans or barrels.

Perhaps this system of management might be called the *gentleman's* system. It certainly is an easy, pleasurable, leisurely way of producing large quantities of first-class honey at a low cost. There is no hurry, hurry, hurry to get the honey extracted because the bees are needing more room; and there is no shaking and brushing of angry bees out in the boiling sun.

#### ONE DRAWBACK TO THE PLAN.

There is just one kind of locality where this plan will not work out so satisfactorily, and that is where the white-honey harvest is followed by a dark flow. We have one apiary in such a location—one where the flow from buckwheat is likely to start in before that from the berries is finished, and we have to watch it very closely and hustle off the white honey the very day that the bees show a tendency to begin work on the buckwheat. It does not take very much dark honey to give some color to a whole lot of white honey. Work it the best we can, there will always be some berry honey not ready to extract, and we are compelled to leave it on the hives to go in with the buckwheat. A fall flow of honey, even if dark, is considered a great advantage, and usu-

ally it is, but I am not certain but I should prefer a locality without the fall flow, simply because it would allow me to put in practice my system of management whereby I could take care of so many more apiaries than with the management that requires the removal of the white honey before the close of the harvest.

Having gone briefly over the plan, and shown that the principal features of the combination are plenty of combs and supers, and the use of bee-escapes and artificial heat in extracting, let's go back to the beginning of the season and take up the work, step by step, and give the more important details.

#### SECURING WORKERS FOR THE HARVEST.

When taken from the cellar, the stores of the colonies are equalized and the hives protected by being wrapped in tarred felt. No more attention is required until it is warm enough to remove the tarred felt. More equalization of stores may be needed, or, if there is a general shortage, some feeding; and it is almost certain that there must be more or less equalization of brood before the opening of the harvest. In a home apiary this equalizing of the brood might not be necessary, but in an out-apiary it goes a long way toward preventing swarming too early, by some of the colonies, and helps to make all of the colonies ready for the same treatment at the same time—a most important factor in out-apiary management.

When all of the hives are comfortably full of bees, brood, and stores, upper stories of combs are added, one on each colony strong enough to need it. No queen-excluder is used at this time. The queen is allowed full swing in both stories, and this abundance of room at this time has a great tendency to forestall the swarming fever. Once the main harvest is on, and the bees at work in two or three stories, the great danger of swarming is past. In an apiary of 150 colonies, managed last year on this plan, only 7 cast swarms.

When the upper story is nicely filled, or nearly filled, with bees, brood, and stores, and the main harvest has fairly begun, a queen-excluder is placed between the two stories. No time is spent in hunting up the queens. We simply wait four or five days, when freshly laid eggs disclose the presence of the queen. As a rule she will be found in the upper story; if so, we simply transpose the two stories, putting the upper one below with the queen-excluder on top, and then set on top what was formerly the lower story. Usually, at this visit most of the colonies will be ready for the third story.

This plan gives the greatest opportunity for the production of a lot of bees previous to the harvest, then curtails the rearing of brood after the harvest has opened, when the production of brood is at the expense of the surplus. As the bees hatch from the combs above the queen-excluder, the cells are at once filled with honey. Many of the colonies will build queen-cells in the supers above the queen-excluder. I have taken pains to go through the supers and tear out these cells, and I have paid no attention to them and allowed the queens to go on and hatch, and I could not see that any harm resulted from either course—that is, there did not seem to be any difference.

As the season advances I keep on tiering up, adding the empty supers at the bottom, next to

the brood-nest. I have often tiered them up three supers high, and, in a few instances, four supers high, with ten-frame Langstroth hives. At such times I have longed for some sort of hive-lifter, and I expect to try one this season.

One object in adding the empty combs at the bottom, and keeping the oldest, ripest honey at the top, is that, if it should be desirable at any time to remove any of the supers of honey, either to extract the honey at once, or because the hive was becoming piled too high, the oldest honey would always be on top, where it could be removed the most readily by the use of bee-escapes.

*To be continued.*

## MANAGEMENT PREVIOUS TO THE HONEY-FLOW TO PREVENT SWARMS.

### Increasing the Amount of Brood Produced Just Before and During the White-honey Flow.

BY E. D. TOWNSEND.

THE CHAPMAN PLAN.

For preventing swarming and for increasing the amount of brood produced previous to and during the fore part of the white-honey flow, Mr. S. D. Chapman, of Mancelona, Michigan, has a system of his own. He uses eight-frame hives, and the system is about as follows: At the approach of the warm period, which is usually near May 20, in this locality, he shakes the bees from two frames of brood, placing these two brood-frames without the bees in an upper story, taking out two empty combs from the upper story to replace those just removed from the lower story. He now puts a queen-excluder on the first story and the second story over it. This gives the queen in the lower story two extra combs to use for breeding purposes; and if there is young brood in the two combs placed in the upper story, this extra space in the two combs amounts to considerable. In a week or two, two more frames of brood are lifted up into another or third upper story, making a three-story hive. This method of lifting brood from the brood-nest into upper stories is continued until it is desirable to curtail brood production on account of the bees not maturing in time to be honey-gatherers.

During 1906 Mr. Chapman lifted brood according to this plan in three-fourths of an out-yard, when it turned cold and a strong northwest wind came up. On the colonies in the remaining fourth of the yard he put on the upper stories, but placed in them no brood. These last colonies were as good as the average of the yard. Shortly after the beginning of the raspberry flow he found that those colonies in the three-fourths of the yard, where brood had been placed in the upper stories, had from fifteen to twenty pounds of honey to their credit, and this gain remained throughout the season.

By following this plan, whole yards of bees have been worked for extracted honey through the whole season, without a single swarm issuing. It can be seen that powerful colonies need more room during the period just before and during the fore part of the white-honey flow than is provided in the ordinary hive in use to-day, and the

above plan shows at least one method that may be employed with regular hives to provide this extra room at a time when it is necessary. Of course, when this time is past, the hive is brought back again to its normal size.

In the fall of the year 1906, during the early part of the buckwheat flow, our Pine Lake yard of 100 colonies was left without upper stories until the hives were crammed full of this early buckwheat honey for winter stores. At this time some of the most advanced colonies built comb and stored honey on the outside of the hives, and some of them must have had as much as 35 pounds of honey in the hive when they went into winter quarters. This was more honey than we were in the habit of leaving, and was even more than a ten-frame hive could hold and still leave room for the colony to breed up in the spring. The consequences were that, when the upper stories were given in May, 1907, before the honey season opened, these bees in the Pine Lake yard carried a few pounds of this buckwheat honey in the brood-nest into the upper story to make room for the queen below, with the result that, when the honey was extracted, it was amber in color and had to be sold for one cent a pound less than the rest, which contained no dark honey. This is the only case of the kind that has come to my notice, and even this would not have happened under normal circumstances.

When I first began to produce extracted honey the plan then in vogue was to lift a frame of brood into the upper story to start the bees to work there immediately. While this was successful so far as getting the bees to work in the supers was concerned, yet it was a noticeable fact that the honey produced by this plan was never quite as good in color as when no brood was lifted above. I soon learned that it is not necessary to lift brood above to get the bees to working in the supers, drawn combs being found sufficient. Now, in lifting this frame of brood into the upper story there was always more or less honey from the previous season lifted with it, which honey was often gathered from buckwheat. This brought about the same result as that outlined above, and the off grade of honey being not to my liking the system was abandoned. This is the worst feature about the Chapman system, for the old honey that is likely to be lifted up with the brood causes all the honey to be of a somewhat darker color and perhaps of a poorer quality.

THE COVEYOU PLAN.

Mr. E. E. Coveyou, of Petoskey, Michigan, has a very good plan for handling his bees during the fore part of the honey-flow. He uses ten-frame hives, and before the honey-flow he gives the colonies another story of combs without putting an excluder between. The cells of these combs should be of the worker size, for the queen is allowed full sway through this story until the colony needs a first one. At the time this third story is given, the queen is placed below in the first story, a queen-excluder is put on, and then the third story of empty combs put over it. Finally, on top of all, the second story partly full of honey and brood is added. This plan has the advantage of giving the colony an abundance of comb room and also an unlimited amount of breeding-space for the queen during the critical swarming period previous to the hon-

ey-flow. This is one of the best systems I have heard of to be used for this purpose in connection with the queen-excluder, for, aside from the advantage gained by allowing the queen unlimited breeding-room during the early part of the season, all of the advantages of the excluder are secured in extracting-time, for the brood lifted above with the second story will all be hatched and the combs filled with honey long before extracting-time, for Mr. Coveyou does not extract until late in August—perhaps 30 days after the close of the raspberry flow.

Before putting on any upper stories Mr. Coveyou clips his queens, for he works three yards practically alone with the exception of extra help made use of at extracting-time, or when some extra work is to be done. By having his queens clipped, and by being with the bees every day during the swarming or honey season, he can have any swarms that may issue. It is obvious that, if the queens had not been clipped, the swarms would have gone to the woods and been lost. If a swarm should issue when he is working at some other yard, and returns to the hive, he is very likely to reach this yard by the next day; and when they come out again, as they almost assuredly will, he can have them.

#### PUTTING ON EXTRA SUPERS.

Knowing by experience that bees will enter upper stories without any hesitancy when placed on top of the hive or on top of any story that may be already on the hive, and as our extracting is not done until after the white-honey season is over, we have no lifting of full stories except at extracting-time. We put on the third story, when the second one is about two-thirds full, or at least before all the empty comb-room is used. However, no set rule can be given as to the proper time for putting on extra supers, as there is a difference in the colonies in this respect. Some bees will work in a few combs and begin to cap those started first, while those combs at the outside of the super will not be in use at all. In such a case it would be folly to put on another super as long as this condition continues. Other colonies will fill every available cell with honey before commencing to draw out the combs or to cap the cells. Such a colony will need more extra comb-room than the one first mentioned, for in the first case the bees seem to be more adapted to working wax and drawing out combs. It is well to humor these dispositions, and not compel the bees mentioned in the last case to draw out the combs to the full capacity of the space allowed. They should, instead, be given additional comb-room as they are able to use it, and they will store much more honey than if compelled against their will to draw out cells to the full depth at once.

At extracting-time, if one wishes to make two grades of his extracted honey all of the partly filled and unsealed combs will be in the top stories if the plan just outlined is followed, and these can then be taken off and extracted by themselves. I believe this to be the ideal way, for the first-given supers are filled out more fully and capped more evenly than if they were lifted up and the empty one placed beneath them next to the brood-chamber. Then with this latter plan of lifting the full supers up and putting the empty supers next to the hive one is likely to

give additional room faster than the bees really need it, with the result that the honey is capped over when the combs are thin, and even when some of the outside combs may not be entirely finished.

Putting empty stories on top is probably the only practical way to manage when a queen excluder is not used between the hive and the supers. If the extra supers are added intelligently when the season is near the end, by giving the colony only what storage room it will need, the queen will thus be crowded down into the hive below, leaving the supers nearly free from brood. In order to follow this method one should bear in mind that it is part of the system, in that the amount of brood in the upper story is to be curtailed toward the close of the season, as explained, and then the honey left on the hive a week or two after the close of the season, to allow it to cure thoroughly. Incidentally, the brood that may be left in the upper stories has thus hatched out before extracting.

The old orthodox plan of placing the empty super above the queen-excluder and under the partly filled one is still practiced by the majority of Michigan bee-keepers; and when the first one is about two-thirds full it is lifted up and an empty one placed beneath. This plan is continued clear through the season, the advantage claimed for this system of extra work being that, by lifting up the full stories and placing the empty ones next to the brood-chamber, the bees are stimulated to greater activity by this dividing of the hive when placing the empty combs next to the brood-chamber. Now, while I admit that it may be advisable to put an empty *comb-honey* super next to the brood-chamber, after a long experience I fail to see where the advantage is in the production of *extracted* honey, and where there is any gain in lifting up heavy upper stories during the honey season, especially when the extracting is all done at one time.

#### THE USE OF AN EXCLUDER TO PREVENT BROOD IN THE SUPERS, AND HOW BY THEM A WHITER HONEY IS SECURED.

Before leaving this subject I would say that, if one does much extracting during the honey-flow, or in the case of a beginner who has had but little experience, I would advise the use of an excluder, for there must be no unsealed brood in the extracting-combs or the honey obtained will not be of good quality. The very sight of these young grubs floating on top of the honey would be enough to condemn the plan of trying to manage without an excluder. If a visitor should happen to come in, those grubs would, of course, be called worms, and it would not help the sale if it should get out that the honey is "wormy." Then there is the food provided for the larvae, some of which is thrown out with the honey, and this surely makes the honey of a poorer quality. My advice, therefore, is to use an excluder under such circumstances until you learn a better way.

Remus, Mich.

[Since it takes considerable skill to produce extracted honey without excluders, any one who has not worked out a successful system for keeping the queens down had better use the excluders to be on the safe side. It is not often that a queen gives much trouble by going into comb-honey supers.—ED.]

## SOME QUESTIONS I AM ASKED.

### Do Weak Colonies have Good Queens? When to Requeen; Attitude of Farmers toward Bees.

BY E. W. ALEXANDER.

Mr. D. T. Gaster, of Randleman, N. C., wishes me to answer through GLEANINGS the following question: "After weak colonies are built up in the spring, according to your plan, do they usually do as well as other colonies, or should their queens be superseded?"

In answer I will say that I have never had occasion to supersede them oftener than other queens. With us all queens, when two years old, are superseded unless it should be a very choice one. We usually supersede queens for one of two reasons—either on account of their arriving at the age limit, or when we buy bees, as we sometimes do, they have queens of all ages and colors; then we supersede them as soon as possible, and in their place introduce good well-bred Italian queens.

I am often asked if it is not as well or better to buy our queens in the fall, at a reduced price, than to buy them in early summer. That depends wholly on the condition our colonies are in. If the old queen is failing to keep her hive well filled with brood without any apparent cause, then we supersede her in early summer; for if she is kept until fall the colony will have but little brood, will be weak in bees, and the young queen we give them will start so little brood that the chances are the colony will be dead in the spring, or so weak in bees that it will be almost worthless. But if the queens we wish to supersede are in full strong colonies, with their hives well filled with brood, then to buy queens in the fall for these colonies is all right; and if the new queen does not start much brood she will still have a good colony to winter in.

These are very important points that should never be overlooked in superseding our queens. I want a queen to occupy the hive she is to winter in at least 40 days before the breeding season closes. This gives her time to become acquainted with the colony, and fill the brood-nest once or twice with brood. If we all look to this part of our business as we should we shall have fewer weak colonies in the spring, and in the end we shall have more surplus, and secure it with much less labor.

Another question I am frequently asked is, "What is the opinion of the farmers in your locality in regard to the effect of your bees working on their buckwheat-fields?"

Some 25 years ago, when we came to Delanson, it was almost the universal opinion that our bees would injure their buckwheat so as to make the crop almost worthless, but the farmers soon changed their ideas on the subject. The buckwheat here is all thrashed by men who have thrashing-machines, and go from farm to farm thrashing the grain for a stated price per bushel. These men soon noticed that, when they came within three or three and a half miles of our apiaries the yield of grain was much better than outside that circle; in fact, it yielded sometimes nearly twice the amount per acre. This was a

surprise to some farmers. Their orchards also gave them much more fruit. The change of opinion among them has been so complete that they are now anxious to have our bees do well.

I sometimes wonder if there is any other business that has had to go through the mire of ignorance and superstition equal to bee-keeping.

Still another question I am often asked is, "Will the greater part of the honey in the future be produced by the specialist, or by men who have other lines of business to follow in connection with bee-keeping?"

In order to give this question any thing like a correct answer we must not only go back and review the bee-keeping of the past, but we must look upon it in the future as being subject to the same natural laws and conditions as all other lines of business. For some time we have seen a continual concentration of capital in every line of business. The men who have a thorough knowledge of their business, and an unlimited amount of capital, are fast driving the less fortunate out of business, and I can not see how bee-keeping can be an exception.

When I was a boy a large part of our farmers kept a few colonies; but now we seldom see any bees through the country except in large apiaries. And the same change will continue to go on until there will be comparatively few men engaged in the business, and these few will be located in the exceptionally good locations, keeping their thousands of colonies, and having the best of every thing connected with bee-keeping that money can buy; and they will sell their surplus at wholesale to reliable parties, giving them three or four months' time if they wish, which often makes quite a difference in the price favoring the producer. There are many young men now starting in the business who will in time drop out; but some will continue, and they are the ones who will be the honey-producers of the future. They will first work for men having had a long experience until they have a practical knowledge of bee-keeping. Here, among other things, they will learn the value and necessity of a good location. To these they will naturally go, where, with their practical knowledge of the business, they can produce honey at half the cost that the inexperienced man can in an ordinary location.

Delanson, N. Y.

## HEADS OF GRAIN FROM DIFFERENT FIELDS

A HALF-INCH STARTER AT TOPS AND BOTTOMS OF SECTIONS.

Dr. Miller says the bottom starter is his baby. Yes, and a robust one it is too. In his diagnosis of Mr. Pryal's trouble he says in substance, "I am of the opinion that the plan will work as well in California as in Illinois; also that the space between the two starters in this case caused the trouble, and with a space of 1½ inches or so between the starters the bees would lengthen each starter, and, when high enough, why should the lower one not lean over?"

I feel a little timid about clashing with Dr. M.

I will do it this way: If they will topple over with a space of 1½ inches, what will they do with a three-inch space? I am not a convert to the use of full sheets in sections, and use a half-inch starter, top and bottom. I have used many thousands this way, and have never detected any tipsy freaks in the lower starters. In a cool time the bees will invariably begin at the bottom, and in the T super they start earlier than in one with slats. I think they will fill the T super earlier than the others. The T super is warmer. In building up from the bottom the bees start with an extremely broad base, and usually are the full width of the section, or 1½ inches thick when not half way up. They make some drone comb with a perfect union wherever the two parts meet. This building from below, in all cases that I have seen, is caused by lack of heat in the upper part of the super, while the sections or frames are warm close to the cluster. Give me two starters and T supers. I could give some fine samples of up-building.

Corona, Cal.

H. M. JAMESON.

[We would inquire whether this building of the bottom starter first is not unusual. Is it true that the T super is warmer than the other styles? We can see no reason why it should be. It does, however, permit the sections to stand closer to the brood-nest, and this may account for the bees favoring the bottom starter.—ED.]

#### TESTING PURITY OF BEESWAX.

While this pure-food law discussion is on in GLEANINGS as regards buying honey and not knowing whether it is pure or not, how about beeswax? I buy more or less each year, and have read all I can find in GLEANINGS, and will say I believe I can tell adulterated honey before I could beeswax. And after I have bought it and remolded it, how can I come back on the man of whom I have purchased it? He would say, "That's not the wax I sold you." I don't know that I have ever had any impure wax; but there is no telling when I shall get it.

S. A. PALMER.

Liberty Center, O.

[There ought to be no trouble if you keep a small sample of every lot of wax you buy, as we do. If you ever receive any complaints about adulteration, have these samples analyzed; and if you find one or more of them adulterated, hold these parties who sent them responsible, which you can do under the national law. In buying wax, look out for grease, as that is the most common adulterant. Avoid the purchase of cakes of uniform color and size, and submit all samples that do not show the proper fracture or break test to the alcohol and water test. The specific gravity of the mixture is made just dense enough to allow a sample of pure beeswax to sink. Any wax containing paraffine, ceresine, or grease, will rise to the surface.—ED.]

#### HONEY AND SUGAR FROM SUGAR-MILLS; HOW SHALL IT BE LABELED?

Since the pure-food law has gone into effect I don't quite understand the ruling on labeling honey. The honey I sell (which is a very small quantity) is sold just as it is extracted from the hives. The bees are never fed, but there are sev-

eral sugar-houses within a few miles of my bees. How should my honey be labeled so as not to cause me any trouble with the pure-food law?

New Iberia, La.

R. SONNEMANN.

[Under the circumstances we would consider it advisable for you to submit several samples of your honey to the United States Department of Agriculture, Bureau of Chemistry, with an explanation of the conditions surrounding you. It may be that your bees do not gather any of this sweet; or it is possible that they appropriate so little of it that it would not show in an analytical test. If the government chemist advises you that the honey does not come up to the United States standard you will have to label it for just what it is—honey flavored with New Orleans molasses. Such honey ought to have a good market with the large baking establishments. If you sell it, sell it for just what it is; and we think they will take it off your hands at a fair price. It ought to make first-class cakes and cookies.—ED.]

#### A GOOD HONEY-FLOW ON THE ISLAND.

Our new Italians seem to be good workers. To-day, April 20, we extracted 100 lbs. from our island apiary; considerable from two and three frame nuclei. Even the twin nuclei have some combs full. It came from saw palmetto.

Osprey, Fla.

I. T. SHUMARD.

[Since the above was put in type we have received the following:]

*Mr. Root:*—We have extracted 130 gallons of honey this week. From your little friend

Osprey, Fla., April 24. CLARA SHUMARD.

#### MORE ABOUT THE HONEY-FLOW IN FLORIDA.

*Mr. Root:*—All your chickens are doing finely. Their appetites are good. Eggs, 20 cts. We are having a big honey-flow. My colony on scales is averaging 8 or 9 lbs. a day—44¼ lbs. in five days. I am a busy man now.

Bradentown, Fla., Apr. 27. E. B. ROOD.

#### SWEET CLOVER.

I want to say to you that I am a lover of sweet clover. I am interested in it, not only for bees but for hay and for stock of all kinds. It is better for milk and butter than any thing else I can find. My wife says it is better than all other clovers.

G. W. MOURN.

Burrton, Kansas.

#### A FEW BEE-KEEPERS WHO STILL SULPHUR-PIT THEIR BEES.

Although the time has come when hundreds have found bee-keeping profitable, yet I am sorry to say there are quite a number still living in this beautiful State of Oregon who subject their bees to the sulphur-pit.

E. J. JOHNSON.

Hillsboro, Oregon.

#### SWARM TRAVELS 80 MILES.

I notice lately some inquiry in regard to the distance swarms travel. I remember seeing in GLEANINGS some twenty years ago a report of a swarm being traced in a desert in Colorado or Arizona, nearly 80 miles. They rested two nights and went on the next day.

New Hampton, N. Y.

E. D. HOWELL.

## OUR HOMES

By A. I. ROOT

Jesus said unto her, I am the resurrection and the life: he that believeth in me, though he were dead, yet shall he live. And whosoever liveth and believeth in me shall never die. Believeth thou this?—JOHN 11:25, 26.

I presume, friends, you are all more or less familiar with that wonderful 11th chapter of John, in regard to the death and raising to life of Lazarus. Many of you, like myself, are getting along in years. The friends of our youth are dropping away on the right and left all around us; and, as one after another is taken away, a sort of feeling of loneliness comes over us. Only a few of us get to be threescore and ten; and, as we approach that period, sooner or later we take a sober thought—a thought that we do not have in our younger years—in regard to this matter of life and death, especially *death*. What is it? I have spoken several times of the sudden calling-away of those near and dear to me. Two have recently gone out of our office; and during the past winter, while I was absent in Florida, first a brother-in-law and then his wife, my youngest sister. While my mother lived it was the habit of my life to pay her a visit every Sunday afternoon when it was possible; and as she lived with this youngest sister I was sure to see her, and have a talk with her at least once a week. After mother's death I somehow kept up the habit of calling on that sister and her husband Sunday afternoon. I can not remember a time in my life when that sister failed to give me a genial smile and a kind welcome. As she had some pretty strong opinions and convictions of her own, I fear that that smile was not always given to everybody; but when I came around, expectedly or unexpectedly, I always found it.

While in Florida we were informed that "Mattie," as we called her, was very sick with pneumonia. One day while in the postoffice I received a letter telling of her sudden and unexpected death. I put the letter in my pocket, and walked a mile to my home; but some way my intellect seemed dull or benumbed; I could not realize that Mattie *was* really gone from this world. When I came into the house and told Mrs. Root what the letter contained, she burst out crying; but I did not shed a tear. I felt troubled about it; but some way I could not take in or realize that the letter told the truth. I kept thinking that it was a mistake or misunderstanding somewhere; in fact, I took up a daily paper in an absent way and began looking it over. Pretty soon I thought I would go out and take a look at the chickens and see if they were all right. I had got as far as the steps that go down into the woodshed back of the house. I was half way down before my mind seemed to take in fully that this youngest sister was really *dead* and *gone*. She was considered the healthiest one of the whole family of seven children. She has been sick scarcely a day in her life. When a full comprehension of what had happened came over me I dropped on one of the middle steps of the stairs and began to cry. Yes, I cried like a child, in a way I had not done for years past; and that cry did me good. I think my little prayer, "Lord,

help," was uttered (at least mentally) a good many times; and I also prayed, as I have been doing so much lately, that I might be able to take in and learn the lessons the dear Savior is constantly striving to teach us.

Well, this event, and the further knowledge that others had died while I was absent from my northern home, has turned my attention to the text I have chosen to-day. The text embodies that wonderful promise—perhaps the most wonderful and difficult of comprehension of any among the precious promises the Bible contains. Let us go over the circumstances a little.

Martha, the housekeeper, as you will remember, as soon as she heard that Jesus was coming, went out to meet him while Mary remained in the house. Martha's first greeting was, "Lord, if thou hadst been here my brother had not died." Please notice that Mary uses the same words when she met him later on. They could not understand how it was that, when they had sent word to him four days before, he had so long neglected or delayed to come to the rescue of that brother whom they loved. Martha had faith, we know, even if she was such a diligent housekeeper, for she says, "I know that even now whatsoever thou wilt ask of God, God will give it thee." Does not this indicate that she had a sort of glimmering faith that he probably *had* power to raise even the dead? and did she know of any case in which he had raised the dead before this time? When Jesus told her that Lazarus should rise again, she replied, "Yes, I know that he will rise in the resurrection at the last day." We gather from this that the Jewish people had a belief or faith in the judgment day. Although the Old Testament does not tell us much about it, they expected and looked forward to a future life. Then we come to the wonderful words of our text—"I am the resurrection and the life." This is the part of the promise I have been trying, sometimes almost in vain, to grasp and comprehend and *believe*. This resurrection that all mankind has looked forward to, more or less, is not only under the direction and control of the Son of God, but he *is* the resurrection and the life. And then comes the rest of our text: "He that believeth in me, though he were dead, yet shall he live."

This last does not seem to require so much faith, because it might be only a promise that he should live again in the judgment day; but the 26th verse says, "Whoso liveth and believeth in me shall *never die*," and that is the most astounding and wonderful of all. I am not a theologian. Very likely I have not gotten things right; but the great truths we are searching for and trying to grasp, I am sure, do not depend very much on whether we all think alike or even have things *right* or not. As we come to mature years we have a sort of judgment and wisdom given us that does not come to us in our younger days. I do not think the younger people will quarrel with me about this. Old age has taught us lessons. Watching the great wide world, especially in a prayerful attitude, has taught us lessons and given us wisdom. A man who has had experience in things of this world can give a pretty fair judgment as to what is best to be done in a case of emergency. Now for that wonderful promise. I do not understand, and I think that very few will understand, that the dear Savior meant

to say that if our faith is sufficient we shall never die a physical death. We must all die of old age sooner or later; but the inspiring promise in these last words as they come to me is that this physical death shall be *bridged over*, as it were, by faith.

And now we come to something that is very hard to comprehend. Perhaps it is not God's will that we ever *shall* comprehend it. Some Christians die apparently without pain. Many of them, we are told, die rejoicing. Of a few, perhaps, it may be said their dying hours were expressed in that other wonderful passage where Paul asks, "O death, where is thy sting? O grave, where is thy victory?" Those whose dying hours are described in the above may fairly be said to "never die."

My good father had no such faith as did my mother. He was doubting and stumbling all his life. Again and again she by her strong faith, that never wavered, lifted him up and planted his feet on solid ground. Well, there was no suffering in his dying hours. I held his hand to the last, and there was no struggle or gasping for breath. His last words were quiet and tranquil, and his face had a peaceful and happy look, long to be remembered by those who saw it; and yet that good mother, whose life was a beacon star to the father and to all of us seven children, died after much prolonged suffering. I was absent when she neared death, but reached home in time to have her express her thanks that I could be near her in her last hours. I have seen other deaths, where it was like an infant going to sleep, and still others where there was great and prolonged suffering. Now, I firmly believe that whosoever liveth and believeth, and accepts the Lord Jesus Christ as the Son of God, shall never die spiritually; but I can not think that Jesus meant we should all be spared the pains and agony of death. I do believe that, with the progress we are making in the way of prevention if not cure of painful diseases, much of the suffering that comes with sickness and death will be done away with; and a faith in God, and an earnest desire to learn these things we are slowly learning, will do much to avert sickness and pain. I do believe in prayer. Even though I can not accept Christian Science and all that is said and written about "faith cure," I can say with a clear conscience that, in my prayers for help amid all kinds of suffering, I can scarcely recall a time when help was not given sooner or later.

Yesterday morning a stranger came into our office, wishing to renew his subscription to GLEANINGS. They sent him over to the desk where subscriptions are received. I overheard him saying something about A. I. Root; but as I had some complicated matter in my fingers at that time I delayed going over to where he stood; and I do not know but I was tempted to think somebody else could wait on him as well as not. Pretty soon he came my way a little hesitatingly. When he told me that he knew me personally more than forty years ago, and had been reading our journal for years, I asked him if he would not like to look over our establishment. I thought, however, he did not seem to be as much interested as many are with the machinery, the buildings, and the busy workmen. Finally he said something like this:

"Mr. Root, I have long wanted to see you and take you by the hand; and I wanted to try to tell you how your little prayer, 'Lord, help,' that you gave us years ago, has helped me through many troubles and disappointments."

Then he gave me a brief account of some of them. Well, I want to confess to you now that sometimes, and especially of late, I get into trouble, and perhaps suffer real pain for quite a good while until finally I say to myself, "Why, old fellow, you have not even once in this case thought to bring into play that little prayer you recommended so much to everybody else." Then comes the prayer, 'Lord, help,' and in a little time I have surmounted the difficulty and go on my way rejoicing. It does not seem to matter whether it is an automobile that I can not manage, or an outbreak of my old temper that prompts me to think of getting up and fighting somebody in my old age; that weapon, "Lord, help," fits all cases and emergencies.

I am told that my brother-in-law, when near death and suffering great physical pain, said over and over to himself, "Jesus, help!" Although he was not a praying man (that is, so far as we know during a busy life that took him nearly over all the world), I was wondering if it were not possible that he too, in his dying agonies, remembered the little prayer that we have been talking about. As Jesus pardoned the thief on the cross when he uttered that brief prayer indicating a penitent spirit at the last moment, we can be sure that in this other prayer where Jesus' help was implored, his help was given.

Now, friends, God knows how we shall die. A dear friend of mine, when very near death, asked one of the relatives to pray that his passage through the dark valley might be an easy one. In this case the prayer was seemingly granted. Now, while I can not think of finding any fault with such a prayer, I have a sort of feeling that we who are strong men—not only physically strong in body, but perhaps strong in faith—should be ready and willing to bear *our share* of what naturally comes in the way of the pangs of death. The dear Savior said in his dying agony, "My God, my God, why hast *thou* forsaken me?" I think we may safely gather from this that not only did he suffer bodily torture, but he was, through his excruciating agony, perhaps tempted to feel that the great Father who had stood by him through every incident of his life here on earth had finally, at the last moment, turned his face away from him. If he suffered, should not we, who have suffered here on earth for his sake, feel ready and willing to follow him and suffer the agonies as he did—that is, if somebody *has* to suffer? A follower of the Lord Jesus Christ should be *brave*—yes, he should be a brave *soldier*. God does not *always* take the obstacles out of our pathway; sometimes it would seem he prefers to lift us over them, providing always *we* do a good job in the way of climbing over them ourselves. And when I come to die I hope my prayer may be, "Lord, help; if it be consistent with thy holy will that I may be spared these bodily pains, well and good; if not, give me, I pray thee, grace to bear them. And give me of thy Holy Spirit that I may be willing to bear in a manly way the sufferings that our dear Savior bore, and that are common to humanity in gen-

eral." And then I hope I may have strength of *body, mind, and spirit* to say, as did the Savior, "Into thy hands I commend my spirit."

After different ones who were near and dear to us have been called away Mrs. Root has frequently asked the question that has been so much in my own mind—"Are these dear friends permitted to know and see what is going on here in this world after they have left us?" The Bible does not tell us much about it. At the transfiguration on the mount, Moses and Elias came back to earth, and we are told they gave the dear Savior encouragement for his coming trial and suffering. They, at least, evidently knew what was transpiring here. God has, evidently, for some good purpose, kept us in the dark in regard to this matter.\* Jesus once said, "In heaven they neither marry nor are given in marriage;" but, if I am correct, this is almost as much information as he gave us at any time in regard to the future.

Now, I have several times in the past alluded to this wonderful God-given *instinct*, both in man and in the animal kingdom. The chickens have a language that they understand, and which the mother understands, when they are only a few hours old. Instinct prompts them what to do in case of emergency, and *how* to do what is best for them—at least to a certain extent. Instinct also prompts mankind, perhaps not exactly as it does the chickens, but in many ways it is a *wonderful* controlling and directing power. As I grow older this same instinct seems to be still with me, prompting me as it did when a child, telling me how to take care of my God-given body, and, to a certain extent, telling me of the future, what God expects of us, and what we have a right to expect of him. Great writers have frequently rebuked skepticism and infidelity by calling attention to the fact that it would be unreasonable, and not to be thought of for a moment, that God would give this education and drill that we get here in this world, or might get, and then snuff us out with annihilation. I think every intelligent human being, if he will but think a moment, will agree to this. In speaking of suicide, some say that that ends the matter, and some religious denominations, if I am correct, declare that annihilation is the punishment of the wicked. Let me suggest right here that no doctrine in the world would so much encourage the suicide mania, which is getting to be so prevalent, as a doctrine like this, unless it is Universalism. God forbid that any human being may rush to the conclusion that he can cancel all his debts, and obtain forgiveness for all his old sin,

by destroying the life that God gave, and which only God can give. Of course, the Bible plainly teaches us of a future life; but does not instinct also in the way I have pointed, and other ways, offer this same future to all of us?

Three near and dear friends have recently and suddenly been called from this world, and the call came so suddenly that not one of these had time, or it would almost seem so, to bid us good by. It seemed hard, when I came to think of it, and Mrs. Root again expressed my feelings when she said something like this:

"Did they really know they were so near death? and if so, why was there not some sort of good by, or something to make us feel easier and better about it?" And then she added, "Oh, if it were only possible for them to give us just the least bit of message, saying they are at peace, and still remember us all in the loving way they did when they were here on earth!"

Her words astonished me somewhat, because I had been having the same thoughts and feelings. In fact, I had prayed that God might give us light in the matter if it were consistent with his holy will.

I now wish to relate an experience that has given me comfort, and I should like to know if it has been shared by others who have lost dear friends. I spoke in one of these Home papers of a good woman who had been many years in our employ—a devoted Christian woman. She and I had many talks about death. I had promised to call on her the day before she died; but I stupidly forgot it, not knowing, of course, she was anywhere near death. I deeply regretted it, and for many days after that she was much on my mind. Finally I noticed at times, when I was busy at something else, a strange feeling came over me causing me to feel that she was near; in fact, at such times I almost seemed to feel her presence and see her face. A heavenly smile lighted it up, and that glimpse told me as well as any thing but words could tell, that she remembered lovingly all of her old friends and comrades through life. After Mrs. Root's sister passed away I had a similar experience. Something that I can not describe seemed to tell me that she was at peace, and happy, and had in no way forgotten the dear friends whom she had left so abruptly, even though she *had* gone away so suddenly that she did not have an opportunity to bid them good by for ever—no, *not* for ever; that is not the word. It should be "good by until we join the happy throng on the other shore."

I told you how hard it was for me to realize that my youngest sister had really gone. Well, some days afterward came that same longing for some sort of recognition showing that she remembered us, and when busy at work out in the field or with my poultry, when I had not been thinking of her at all, memory or something else would *startle* me by a vision of her old cordial smile and hand-pressure—a sort of assurance, as it were, that she knew how we missed her, and perhaps knew our very thoughts.

Now, these thrills that come to me may be only a memory of the dead; but I can not help taking it as an answer to my little prayer, and that God in his great mercy and loving kindness has permitted me to have just a *little* glimpse of the unseen world to strengthen my faith.

\* In the 16th chapter of Luke, in the parable, we are told the rich man begged to have Lazarus bring him just a drop of water to cool his feverish tongue. Abraham refused to grant the request, giving two reasons for this refusal. First, "between us and you there is a great gulf fixed so that they which would pass from hence to you can not; neither can they pass to us that would come from thence." Then this rich man begged to send a message of warning to his five brethren; but father Abraham says *no* again, and gives another reason—"If they hear not Moses and the prophets, neither will they be persuaded though one rose from the dead."

Now, these two passages may not be intended to teach us that there shall be no communication between the departed friends and this world; but does it not look somewhat that way? There certainly is a "great gulf," as told us in the parable; and I am inclined to think, too, that, even could those come back who have died in their sins, their warning would be but little heeded. God knows we have lessons enough right before us in regard to the consequences and penalties to be paid here in this life to those who deliberately choose sin and crime.

It has been reported, as you may know, that somebody once asked Darwin if he believed that the Creator had ever given us any revelation from the future and spirit world, and he replied he was unable to find any such evidence satisfactory to himself. Some writers have claimed from this that he rejected the Bible and its teachings. I do not take it so. I have read over and over what he said, and I think he intended to convey the idea that, since the day of miracles, or aside from the revelation of the Scriptures, he could find no evidence of any reliable communication from the spirit world. I heartily agree with him in that. What I have just been telling you about has no reference to spiritualism. I do not believe I shall ever have any leaning in that direction; but again and again have devoted Christians told me that, after the death of one of the near and dear ones, God had sent the comforting influences of the Holy Spirit in a way that was just wonderful. My own good mother frequently referred to it after the death of my father. She said she almost felt his presence near her, and so perhaps I have *inherited* something of the same sort.

In the 16th chapter of John you will notice Jesus has much to say about sending the Comforter after his ascension. Now, can we not in closing find additional happiness and comfort in going over once more the words of our text?

"I am the resurrection and the life. He that believeth in me, though he were dead, yet shall he live; and whoso liveth and believeth in me shall never die. *Believest thou this?*"

#### CHICKENS FOR BOYS AND GIRLS, AND FOR ELDERLY MEN AND WOMEN, ESPECIALLY THOSE WHO LIVE IN CITIES AND TOWNS.

I take great pleasure, friends, in showing you a beautiful picture of one of Mr. Philo's houses for six hens, see p. 638. These fowls are a strain of White Orpingtons. They have been kept in these little houses indoors for five generations. They will not go out and run away, even if the door is left open, or at least they did not when I was there. This is the more remarkable because the house is only 3 feet wide, 6 long, and 4 high—5 feet to the peak of the roof. Of course, the proprietor is not supposed to go inside of the house, as the lower story is only 2 feet high, and he might bump his head, although the chickens do not. But the houses are so arranged that he can easily reach every foot of space inside, keep it clean, get the eggs, pat the biddies on the back, give them a kind word, etc. The same building will answer for chickens of all ages.

Well, the first week or two such houses will accommodate 50 or 100 chicks very nicely. When they are too much crowded, just put half of them in a similar house, and so on. Friend Philo thinks one gets enough more eggs with only six laying hens in a house to save the cost of the extra house. If managed properly, one ought to get six eggs a day a good deal of the time; but if you had a house large enough to hold sixty, how long would you have to wait before you got sixty in a day?

The picture is so plain that it almost explains itself. There are doors to the lower story, both front and back. These doors can be held open with a hook so as to give shade when the fowls

need it. Then the poultry-netting frame can be moved out so as to make a little yard both sides of the house. This is an advantage in giving them green food, for lettuce, oats, rape, or other vegetables may be planted in this ground for their special entertainment.

The front roof is in two parts so you can open one to get the eggs without opening the whole roof. The two frames, one covered with cloth and the other with poultry-netting, slide back out of the way. The cloth gives them air without too much of a draft; and it also shades them from the sun when too warm. It gives them more light than when the roof is left on. The gable in full view is also covered with cloth. In winter time an extra cloth tacked on a frame is put over this end, making a dead-air space, and still giving them an abundance of air. The lower part is all used for scratching-pens. The water and food are upstairs, as are the nests. While in Florida I found it quite tiresome to stoop down to the ground to gather the eggs, especially where they were hidden in the bushes or inside of a barrel or other like places. Now, with this arrangement you can get the eggs while standing up straight. The roosts for six hens and a rooster are placed over a light pan of galvanized iron. There is a handle to this pan so you can take it in one hand and lift out the droppings in the fraction of a minute. The bottom of the pan is kept covered with a little dry dust, or, better still, pulverized peat, or swamp muck, that will make the droppings all come off from the pan and leave it perfectly clean.

Now, these buildings need not be expensive. You will notice the front door where it is turned up is cheap half-inch lumber. This lumber is covered with a good quality of building-paper. The whole thing is so light that it can be easily moved along so as to give the fowls fresh ground once a week or oftener if you choose.

Now, then, friends, what girl or boy would not be captivated by such a handsome little poultry-house containing laying hens or chickens of different ages, or all together if you choose? When you live out in the country, where hens can run out without annoying the neighbors, I think you can keep a dozen or more in one of these little houses.

There are quite a few poultry-keepers nowadays who claim they get more eggs from fowls in confinement, where properly supplied with all their needs, than they do where the fowls run loose. I suspect, however, that a small yard for each little house will be better still.

But one thing should impress itself upon all who are keeping poultry. We who are followers of the Lord Jesus Christ should not keep fowls nor any thing else to the annoyance of our neighbors. Years ago my good old friend "Aunt Margaret" said in substance, "Mr. Root, if chickens make my neighbor to offend, I will keep no chickens while the world standeth." Then she promptly sold every last one, and kept no more. I really felt ashamed of myself, and was sorry I had complained, even if her poultry did get over on to our flagstone walks and annoy us. With the above little house, and fowls kept inside or in a secure little yard, there is no danger of their being troublesome to the neighbors or anybody else.

## INCUBATION—SOMETHING YET TO BE DISCOVERED.

Just before I left Florida, one day when I was away from home Charley, our colored boy, found a nest out among the palmettos containing 16 eggs. As he knew we were going away soon he drove the hen off, covered up the nest, and carried the eggs to Mrs. Root. She broke one to see if they were fit for use; but finding they were about a week toward hatching she kept them until my return next day, and then suggested that I could boil them for the young chickens. I said, "Not so. We will put them back in the nest, and let these chickens hatch after we are gone."

"But, my dear husband, they certainly will not hatch, for they were on the bench in the workshop all night, and it was quite cold."

I told Charley to fix the nest as it was, and put them back; but the hen was too badly scared, and paid no attention to them. So they were out another night; but when I found a hen that wanted to sit, I gave her the 15 eggs. Mrs. Root thought I was crazy in thinking eggs would hatch after they had been out in the cold for two days and two nights. But I had read somewhere in a poultry journal that, after eggs had been incubated until the fertile ones could be sorted out, they could be sent by express short distances and still hatch. In this way you need not send off unfertile eggs at all, and have your customer go to the expense of sending back the bad ones to prove that they were no good. Mrs. Root laughed at my pains with some eggs that "everybody knew" could not possibly hatch chickens. Well, my neighbor, Mr. Rood, writes as follows under date of April 15:

"The hen hatched fourteen chickens, and they are all growing finely."

I suppose of course the mild weather of Florida favored the matter; but, if I remember correctly, one of the two nights when the eggs were out of the nest the temperature was somewhere between 40 and 50 in the morning. In view of this, is it so very important that the temperature be kept constantly at 103°? One of the poultry journals says if you let a sitting hen have the eggs for the first week almost any incubator will give a successful hatch. Who knows about it?

## ALFALFA FOR POULTRY, BEES, AND OTHER FARM STOCK.

I take great pleasure in presenting the following, taken from the *Ohio Farmer* for April 25:

Last year I selected a plot of rich garden soil, pulverized the soil as fine as for an onion-bed, then I made shallow furrows two feet apart, and sowed the alfalfa seed in them with the garden-seed drill the same way as onion seed, and about as thick; then I walked over the seed, firming the soil over them. In a week the seed had germinated, so that I could see the plants in the rows. I ran the wheel cultivator between them, removed all the weeds, and replanted vacancies. The wood ashes from the house were scattered between the rows, and the cultivation kept up all summer, and in the early winter the plot was top-dressed with fine manure. I obtained two cuttings the first year, and a second was left on the ground. This season, judging from other plots of alfalfa on my place, I shall cut four large crops. Thus I know from experience that alfalfa is the best food for the poultry, the cow, and the horse, that I ever used. When you have obtained all the milk or eggs you can with other grasses and grain, you can further increase the yield with alfalfa, and the cow will leave all other food for it; and hens that are confined in yards will eat cut alfalfa as readily as grain.

With all my animals, I can reduce the grain feed more than one-half with alfalfa. Here is the solution of the problem of making hens pay on the village lot, if there is a good piece of soil near by where alfalfa can be grown as I have described. I

wish to be understood that one must learn to grow alfalfa, and how to handle it for feed. It never will be easy to start alfalfa on common soil; but give it the same care as the garden crop, and understand that its culture is the highest type of farming or gardening, and that it requires as much skill as to grow fancy strawberries. Study the plant and its needs, then do the work the right way, and there is no doubt about results.

I have a neighbor in the village where I live, who tells me he can show a balance sheet of \$2 profit per hen for one year. His hens have plenty of grass. My friend living in the village of which I have spoken made a profit of only 60 cts. per hen last year. I told him about my experiments in the cultivation of alfalfa. He is going to try growing it in the same way. I believe it possible for him to make as good a showing as my neighbor, whose margin of profit is \$2 per hen.

Delaware Co., N. Y.

W. H. JENKINS,

Now, friends, the above is true—every word of it. Alfalfa is being grown successfully over almost all of the United States. I got a good strong stand on a little piece of ground in Florida by making the soil rich with cow-chips, as I have explained. Of course, it may not be suitable for all soils; but if you find you can grow a little patch of it in your garden you can extend the area and get a good field of it eventually. Please bear in mind that, where it is once well started, it is good for fifty years or more. It certainly is nearer a grain ration than any other clover or grass in the world. Sweet clover may come pretty close to it in value after the stock have once learned to eat it. I do not know about that, but I would urge every farmer or gardener to start a little patch in his garden at once—that is, if alfalfa is not already growing and succeeding in his region. It is the quickest seed to germinate, I think, I ever got hold of. The plants will be up and growing before you know it; and with a very rich and suitable soil, and plenty of water to start with, they will make about the most rapid growth of any plant I know of. Even if you have only a few chickens in town, you want a bed of alfalfa; and it will be just the time to start it when this gets before you. For years we thought alfalfa would not grow in Ohio; but as the people have learned how to handle it, it is now getting to be a success almost everywhere.

## ONE OF THE "STRAWS" WHICH SHOW WHICH WAY THE "WIND BLOWS."

Dear Brother Root:—"Missouri is going dry." The Anti-saloon League is bringing things to pass in this State. We have 76 counties out of 114 in the State; have closed nearly 300 saloons since the first of January. We are distributing 50,000 of the enclosed buttons; will have another 50,000 ready for delivery in July. Yours for the annihilation of the liquor traffic in the nation.

U. G. ROBINSON, State Supt.

St. Louis, April 29.

Perhaps I should explain that the matter on the enamel button inclosed in the above letter reads "Missouri dry in 1910."

Here is another straw. Several Medina people have recently moved to New Mexico, and they have recently sent me a leaflet to let us know how they prosper. It reads as follows:

Artesia was the first town in New Mexico to abolish gambling by law, and on March 3, 1908, by a vote of more than two to one, the citizens banished the saloons. The first town in New Mexico to take such action. Moral: Come to Artesia. This tells you what kind of neighbors you will have.

By the way, friends, there is a big moral right here. Did you ever hear or did anybody ever hear of anybody else boasting that a town had gone wet? How would it seem to hear somebody say, or to see an advertisement (asking people to locate) reading as follows—"Our town has just voted wet two to one"? "

## THE SPIRIT OF "THE GUIDE TO NATURE."

It is the mission of "The Guide to Nature" to draw the reader toward an appreciation of the beauty and value of natural objects and away from artificial objects to the domain of wild nature; to arouse the listless student to activity and zeal in the study of nature.

Even to the most enthusiastic of us who study and love nature, there come times when, after we have "wandered away and away with Nature," we can sympathize with what Longfellow said of Agassiz, that

. . . "the way seemed long  
Or his heart began to fail."

It is at such times that "The Guide" will inspire to greater efforts and encourage every student by telling of the faithfulness, zeal, and success of others. We all need good cheer from fellow-workers. Much of our inspiration is, "Omne vivum ex vivo," which freely translated means, "We are inspired and cheered by a friend." "The Guide" will be a leading, enticing, cheering, encouraging friend to students and lovers of nature.

The manufacturers of a certain "talking machine" advertise extensively that it "saves theater money." The publishers of "The Guide to Nature" can excel that by at least one point, and may well advertise that it "saves theater desire"—makes the theater expense wholly uncalled for, and that, too, in the best way, not in substitute on a small scale, but an excelling on a larger and better point of view.

There is no entertainment, no interest, no education, no resource equal to nature when rightly viewed. "The Guide to Nature" directs you to that view.

You who find entertainment and interest in honey-bees need no further argument. You are of the right mental make-up to understand all I would say if I wrote volumes on nature as a recreation. All you need to do is to send \$1.50 for a year, or 15c for a single copy.

EDWARD F. BIGELOW, Editor of "Guide to Nature,"  
Stamford, Connecticut.

## WE WILL SEND TO YOU FREE.

This handsomely illustrated, fifty-page booklet containing a most interesting description of the famous Manatee section, being a reproduction of a series of articles written by the editor of one of the leading agricultural papers in the United States after a personal investigation by him. The articles were run in serial form in his publication during the last four months, and we have embodied same in an attractive pamphlet, illustrating it with dozens of interesting and instructive scenes from actual life. This handsome piece of literature will be thoroughly enjoyed and worthy of preservation, and will be sent free, together with pamphlet containing a list of properties available in the LAND OF MANATEE upon receipt of five cents in stamps or currency to cover cost of mailing. Our supply of this booklet is limited, and if you want a copy you should not delay, but write at once.

## A NEW HIVE-TOOL

Hitherto we have said very little about our new hive-tool, but after submitting it to some of the foremost bee-keepers of America for their candid opinion—for or against—the universal verdict is that it is a good thing; though it looks like a very simple tool it is very surprising how useful it is to an apiarist. The bent end, for example, is just right for severing Hoffman frames. A slight twist of the wrist does the business without angering the bees, and one's hand is so placed the bees do not see it. For scraping wax and propolis nothing could be finer, and it is better than a chisel, screwdriver, or putty-knife for opening hives. Any bee-keeper will be glad of one in his pocket ready for all occasions. It is made of the finest hardened steel nickel plated.

### Sample Testimonial:

*Mr. Root:*—I have been using your nickel-steel hive-tool this spring, and am very much pleased with it. It is the best thing I have tried yet. I, with my helper, have been using tack-pullers heretofore; but this is better because so much stronger. It leaves nothing to be desired except that there should be a hole in it a little nearer the crooked end. I tried to get one drilled but had to give it up—too hard; so I fastened a strap around it to fasten to my pants button.

## ITALIAN

## Queens

and bees, and nothing but Italians. An improved superior strain is what QUIRIN-THE-QUEEN-BREEDER raises. Our stock is northern-bred and hardy. We just visited our outyards (all wintered on summer stands), and not a colony is dead to date (March 18). Some hives have lost scarcely a bee, so it appears. BROTHER BEE-KEEPER, how do you like such stock for hardiness? A party up in Maine got 50 nuclei of us several years ago. We just received a letter from him. He is after more of our bees, because last season he got 2200 pounds of honey which sold for 22 cts. per pound. Our stock is well known throughout the United States. Some of the largest yields reported can be traced to our stock. Over 20 years a breeder. Free circular and testimonials. Price of stock as below.

| Prices of Queens before July.           | 1      | 2      | 12      |

Tested queens in May and June, \$1.50; after July 1st, \$1.25. Two-comb nucleus, no queen, \$2.00; three-comb nucleus, no queen, \$2.50. Full colony on eight frames, no queen, \$5.50. Five per cent discount on five, ten per cent on ten or more.

CATALOG FOR 1908 FREE. SEND FOR ONE.  
GEO. W. BARNES, box 340, NORWALK, OHIO

## ITALIAN QUEENS

Having purchased the apiaries and queen-rearing business of Mr. A. E. Titoff, at Ioamosa, Cal., I hereby politely tip my hat to the bee-keeping world and try to say that I shall use every endeavor in my power to serve you faithfully and honestly.

Send for circular and price list.

Yours for the best queens and bees,

**E. M. GRAVES,**

**Ioamosa, San Bernardino Co., Cal.**

## Westwood Red-clover Queens

Are the bees that got the honey in 1907. Better try them for 1908. Nuclei and full colonies a specialty. Price list on application.

HENRY SHAFFER, 2860 Harrison Ave., Sta. L, Cincinnati, O.

## PHARR'S GOLDENS

took first prize at three exhibits in 1907. We also breed Carniolans, three-banded Italians, and Caucasians, bred in separate yards and from the best breeders obtainable; guarantee safe delivery and fair treatment. Untested, 75 cts.; tested, \$1.00.

New Century Queen-rearing Co., Berclair, Tex. John W. Pharr, Prop.

## W. H. Laws

is again on hand for the coming season with a larger stock of queens than ever before.

He sold 400 queens to a New Mexico producer last May who wrote, "Your stock is far ahead of those Eastern queens I have been buying," and has placed his order for 1000 more of the Law queens to be delivered in May and June coming.

Others write that, if they had purchased all Laws queens, their crop of honey would have been doubled. Testimonials enough to fill this book. If you are going to improve your stock, had you not better investigate?

Single queen, \$1.00; dozen, \$10.00; breeders, the best, each, \$5.00. W. H. LAWS, Beeville, Bee Co., Texas.

## ITALIAN QUEENS BY RETURN MAIL OR MONEY REFUNDED.

Warranted, \$1.00 each, six for \$5.00; tested, \$1.50 each. Circular free.

D. J. BLOCHER, PEARL CITY, ILL.

## MILLER'S SUPERIOR ITALIAN QUEENS

By RETURN MAIL; bred from best Red-clover working strains in U. S. No better hustlers; gentle, and winter excellent; untested, from my SUPERIOR breeder, 1, \$1.00; 6, \$5.00; 12, \$9.00. After July 1st, 1, 75c; 6, 4.00; 12, 7.50. Special prices on lots of 50 or more. Satisfaction and safe arrival guaranteed. Circular free. ISAAC F. MILLER, :: Reynoldsville, Pa.

## FINEST POSSIBLE BREEDING

BRED BY

**F. J. WARDELL,**  
UHRICHSVILLE, OHIO, U. S. A.

After many years' experience as head queen-breeder for The A. I. Root Co., I am now breeding bees at the above address. My stock is equal to any now advertised, and my long experience enables me to judge very accurately the value of any strain. Mine is the celebrated red-clover stock, which has given so much satisfaction to thousands of buyers for a number of years past. If you desire something very select for breeding purposes, write to me, stating your wants, and the same will be supplied. I have no cheap or inferior queens to sell. My prices for the season are as follows:

|                                  | May to June.      |
|----------------------------------|-------------------|
| Untested queen . . . . .         | \$1.25            |
| Select untested queen . . . . .  | 1.50              |
| Tested queen . . . . .           | 2.50              |
| Select tested queen . . . . .    | 3.50              |
| Breeding queens . . . . .        | 6.00              |
| Select breeding queens . . . . . | 9.00              |
| Extra select . . . . .           | 1 year old, 12.00 |

No untested queens sent before May 15; but to secure your queens early in the season it is necessary to order now. Absolutely, all orders filled in rotation.

# 5000 QUEENS

of the famous 3-banded LONG-TONGUE RED-CLOVER STRAIN OF ITALIAN BEES is what I want to sell this season.

My bees GATHER HONEY if there is any to get; ARE LITTLE inclined to swarm and sting; they please such people as The A. I. Root Co., R. F. Holtermann, W. Z. Hutchinson, Morley Pettit, etc., and if they don't please you, send in your kick.

Queens of all grades now ready.

|                             | 1      | 6      | 12     |
|-----------------------------|--------|--------|--------|
| Untested queens.....        | \$1.00 | \$5.00 | \$9.00 |
| Select untested queens..... | 1.25   | 6.00   | 11.00  |
| Tested queens.....          | 1.50   | 8.00   | 15.00  |
| Select tested queens.....   | 2.00   | 11.00  | 20.00  |
| Breeders, \$5.00 to \$7.00. |        |        |        |

W. O. VICTOR (Queen Specialist), Hondo, Tex.

## When You Need Queens and want Your Order Filled By Return Mail.

Three-band Italians bred for business. Tested, \$1.00; untested, 75c; \$8.00 per doz. Send for price list.

**J. W. K. SHAW & CO.,**  
Loreauville, Iberia Pa., La.

## SPECIAL NOTICES

BY OUR BUSINESS MANAGER

### FOUNDATION SPLINTS.

Some have been writing Dr. Miller for foundation-splints. He does not have them for sale. We are prepared to furnish them for 10 cts. per 100, 50 cts. per 1000 postpaid, or 40 cts. per 1000 with other goods.

### MAPLE SYRUP.

We have a good supply of very choice maple syrup which we can supply at \$1.00 per gal.; 6 gal. at 95c; 20 gal. or over, 90c. Will be pleased to hear from those interested. Maple sugar is not so plentiful, and we can not offer this at less than 15c per lb. for best; 13c for fair to choice.

### CARTONS FOR OUNCE CAKES OF BEESWAX.

We can supply cartons for one-ounce cakes of beeswax, printed with name and address blank, at 35 cts. per 100; 250 for 80 cts.; 500 for \$1.50; 1000 for \$2.75; by mail, 15 cts. per 100 extra. These prices will also include the large carton to contain 32 of the small ones. The complete package weighs 2 lbs., and, when filled, sells to the dealer at \$1.00. They retail the cakes at 5 cts. each. Retained molds for molding ounce cakes costs 35 cts. per dozen; by mail, 40 cts.; for two-ounce cakes, 40 cts.; by mail, 50. We do not have cartons to fit the two-ounce cakes. To print your name and address on the cartons will add, 250 or less, 50 cts.; 500, 75 cts.; 1000, \$1.00.

### SECOND-HAND FOUNDATION-MILLS.

We have to offer the following second-hand foundation-mills in good condition. We shall be pleased to hear from any one interested. To such we can send a small sample of comb foundation representing the kind of work produced by the particular machine you inquire about.

No. 079.—6x2½-inch hex. cell thin-super mill, in very good condition. Price \$12.00.

No. 078.—6x2½-inch hex. cell thin-super mill, in good condition. Price \$12.00.

No. 086.—6x2½-inch hex. cell extra-thin-super mill, in good condition. Price \$12.00.

No. 075.—2x9 hex., very old style, on frame with wood base; in fair condition. Price \$10.00.

No. 085.—2½x6 hex. thin-super mill, in good condition. Price \$12.00.

No. 086.—2½x6 hex. extra-thin-super mill in extra-good condition. Price \$15.00.

No. 096.—2½x10 hex. light-brood mill; almost new; in fine condition. Price \$20.00.

No. 097.—2½x10 hex. light-brood mill; in fine condition. Price \$18.00.

No. 077.—10x2-inch medium-brood round cell, old-style frame, in good condition. Price \$14.00.

No. 092.—6x2½-inch hex. cell extra-thin-super mill, in fine condition. Price \$15.00.

No. 2275.—6x2½-inch hex. cell extra-thin-super mill, in good condition. Price \$13.00.

## Special Notices by A. I. Root

### GOOD BOOKS FOR BEE-KEEPERS AND OTHERS WHO ENJOY OUTDOOR WORK AT THIS SEASON OF THE YEAR.

Don't forget to look over our list of books elsewhere in this issue. It should have been put in a little earlier, but was crowded out by other matter. Many of these books will give you short cuts in your outdoor work that may save you hundreds of dollars. They are all carefully selected, and some of them were written by your old friend A. I. Root, some of which, at least, he thinks, will prove valuable. I want to call attention also to our free leaflets and pamphlets. These were printed to give away free of charge in order to save our time in answering many questions that are asked over again. Some time later on, if you write that these leaflets have been helpful to you in the past, that will be all the pay we want.

### THE "FIRELESS" BROODER UP TO DATE.

The one we have works beautifully in April and May. While we gave the chicks the benefit (?) of the warm pipes in the greenhouse they kept dying as mentioned in our last issue; but after we put them outdoors where they had no artificial heat at all they brightened up at once and not a chicken has died since; and I feel pretty well satisfied that no artificial heat is needed (in fact, I

think the chicks are much better off without it) say after April 1 in our locality. Perhaps there is no artificial heat needed, even in the winter time; but I am not so well satisfied from my own experience as to that; but I do now feel very sure that, in my travels, I have seen many chickens feeble and dying under the influence of artificial heat when they would have been *ever so much* better off out in the open air and sunshine.

### A NICE LARGE POULTRY-BOOK ABSOLUTELY FREE OF CHARGE TO EVERYBODY WHO SUBSCRIBES FOR GLEANINGS.

This book is the same thing that is advertised on page 661 at \$1.00. There are 350 pages, profusely illustrated, and it is exactly the same thing as the dollar book except the paper covers. Everybody who sends a dollar for GLEANINGS, or any one who pays for it a year or more in advance, may have this book free of charge providing he sends 6 cents to pay the postage. We furnish the book just as we say, but we positively can not keep postage-stamps to give away. Although this book may not be clear up to date in some things, it contains more *practical matter*, in my opinion, than a whole dozen of some of the little paper pamphlets now offered for a dollar or more.

### THE "DANDELION COW" AT THIS TIME, MAY 15.

This same cow is now giving a foaming pailful of excellent milk while her food is almost entirely dandelions and nothing else. While I write she is gathering in the yellow blossom-heads in great quantities, that stand a foot high or more, and cover the ground in our orchard so thickly that in places they look as if the ground were literally covered with yellow snow. Just at this time I notice the papers are (as usual) talking about waging war on the dandelion. Why in the world don't they get a cow, and then, instead of fighting the dandelions, underdrain the soil and make it very rich, and let the dandelions grow? There is no other plant that will furnish the amount of feed at this season of the year as does the dandelion. We (Roots and Rootlets) have not found any better milk than that furnished by the cow while she is, week after week, on an almost pure "dandelion diet."

### WRIGHT BROTHERS MAKE A SUCCESSFUL TRIP IN AIR-SHIP.

I have been telling you several times of late that we should soon have some news. As I write to-day, May 9, the daily papers are full of accounts of their flights. From a column of matter in the Cleveland *Leader* I gather that they are making some flights from Manteo, N. C., over the sand dunes of what is called Kill Devil Hill. They have made as many as ten ascensions, covering in all over 30 miles. Every thing worked quite as well as when I witnessed their work two years ago last October. First one of the brothers made a flight and then the other. They seemed to show equal skill in handling the machine. "At no time did it seem necessary to direct the machine to the ground. Apparently it could easily have continued its flight many miles." Their longest flight, which occupied two minutes, covered a mile and a half. The papers state that the present machine weighs 350 lbs. The engine, 30 horse-power, weighs just about as much as the rest of the machine. I quote from the *Leader* as follows:

The Wrights refuse requests for information regarding their machine, and little can be learned about it except by observation of its performances. Located as they are at Kill Devil Hill, and surrounded by sand hills with practically no inhabitants, their experiments were witnessed by only a few people. They are one mile from the Kill Devil Hill life-saving station, on the beach of the Atlantic. Its six surmen assisted them in building and in handling the machine. These and several others witnessed the experiments to-day.

A herd of long-haired cattle, observing operations from afar, were frightened into Roanoke Sound when once the machine flew in their direction.

Probably by the time this reaches you there will be plenty of news of a more extended flight. May God grant that no accident may happen to these two young Ohio inventors who seem to have distanced the whole wide world in making a machine that will actually fly like a bird, without the assistance of any balloon.

I have had no recent information from the Wright Brothers themselves; but the above would indicate that there is going to be "something doing" pretty soon in the way of a real flying-machine—that is, a machine that does not need a balloon to hold it up.

### DAY-OLD CHICKS BY EXPRESS.

Dear Friends:—I will say I make a specialty of shipping day-old chicks by express. I am a subscriber to GLEANINGS from the start, and will be as long as I live. H. M. MOYER. Bechtelsville, Pa.

In addition to the above we would add the names of Mrs. Stephen Walker, Hawthorn Farm, Williamsville, N. Y.; and F. E. Schriver, Greenlawn Farm, Grafton, O., sends out day-old chicks and ducklings; also C. A. Thompson, Bellevue, O., and F. G. Mason, Fabius, N. Y., chicks only.

## Convention Notices.

### TENNESSEE STATE BEE-KEEPERS' ASSOCIATION.

At the close of the course in apiculture given at the University of Tennessee, Knoxville, this spring, a State bee-keepers' association was formed. The following officers were elected: President, Prof. G. M. Bentley, Knoxville; Vice-president, Mr. Henry Cook, Springfield; Secretary and Treasurer, Mr. John Davis, Spring Hill. Much enthusiasm was demonstrated in the organization of this Association, and the list of membership has increased rapidly, and additional names are being received daily. The annual meeting is to be held conjointly with the State Horticulturists and Nurserymen in Nashville during the last week in January, 1909.

G. M. BENTLEY,  
Ass't State Entomologist and Plant Pathologist.

[The bee-keepers of Tennessee would do well to get in touch with Mr. Bentley.—Ed.]

The annual meeting of the Missouri State Bee-keepers' Association will take place May 26 and 27, at the Courthouse of Carrollton, Mo. The meeting will convene at 9 A.M.

A very interesting program has been prepared which is as follows: First day, morning session at the courthouse; afternoon meeting at the bee-yard of A. Finlayson, of Carrollton. There will be a practical demonstration of transferring bees from box to movable-frame hives, and a practical demonstration of queen-breeding and requeening colonies of bees.

Second day at courthouse. Lecture on foul brood, explaining the same by exhibiting a hive containing diseased combs, also microscope and slides showing the microbes which cause the disease.

Our State bee-inspector, Mr. M. E. Darby, will be on hand to explain the spread of the disease over our State. There will be a number of speakers, all expert bee-keepers, who will lecture on different topics interesting to bee-keepers.

We also expect to exhibit in the courthouse yard a hive of bees in a cage made of wire screen to enable the public at large to see the working of the bees without being in danger of stings. An expert bee-keeper will enter the cage, open up the hive, and show how the bees are doing their work.

Hotel accommodations can be had at \$1.00. Arrangements have been made so that all can be accommodated. All bee-keepers and those interested in bees are invited.

ROBERT A. HOLEKAMP, SEC.,  
4263 Virginia Avenue, St. Louis, Mo.

## T. B. TERRY'S HEALTH HINTS

published only in The Practical Farmer each week, have been the means of saving lives and thousands have been helped to enjoy life more than they have ever done before. | For several years we have been unable to get a nice substantial copy of this book at a reasonable price. We are glad to tell our friends now, however, that we have a very pretty edition, bound in cloth, at the very reasonable price of 25 cents. If wanted by mail, add 6 cents for postage. This book has had a very large sale for more than 20 years, and when I tell you that quite a number of people have been converted to the Lord Jesus Christ simply by reading it you will no longer wonder why it sells. At one time it was carried and sold by the newsboys on our railways. It not only contains a wonderful "secret" for unbelievers, but for many who have been church-members all their lives, but not the "happy" church-members that God intended we should be. |    |
| 5   Amerikanische Bienenzucht.....                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | 95 |

| This is a story of the life of the bee, told in very interesting style—how it lives, gathers honey, and all about it. While clothing the general subject with an air of poetry, it seems to be entirely within the limits of known facts while attempting to deal with them. We believe it will give all thoughtful bee-keepers a greater liking for their business to read it. Probably it has more to do with the curious traditions connected with bees than any other book of the kind. |      |
| 10   The Life of the Bee.....                                                                                                                                                                                                                                                                                                                                                                                                                                                               | 1 30 |
| Thos. Wm. Cowan, editor of the British Bee Journal, in his review of Maeterlinck's work, says: "Not since the appearance, in 1876, of Bucher's 'Mind in Animals' have we had a book about bees more charming, or one that we have read with greater pleasure, than Maeterlinck's 'Life of the Bee.'"                                                                                                                                                                                        |      |

| The first really full and complete book on celery culture, at a moderate price, that we have had. It is full of pictures, and the whole thing is made so plain that a schoolboy ought to be able to grow paying crops at once without any assistance except from the book.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                         |

| This book ought to save at least the money it costs each year, in every household. It was written by a doctor, and one who has made the matter of domestic economy a life study. The regular price of the book is \$1.00, but by taking a large lot of them we are enabled to make the price only 30 cents.                                                                                                                                                                                                                                                                                                                                                                                                                                     |                         |
| 10   Fruit Harvesting, Storing, Marketing, etc.....                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | 75                      |
| It has been well said that it is an easier matter to grow stuff than to sell it at a proper price after it is grown; and many men fail, not because they are inexperienced in getting a crop, but because they do not know how to sell their crops to the best advantage. This is the first book of the kind we have had as an aid in selling. It not only tells all about picking, sorting, and packing, but gives all the best methods for storing for one or two days or a longer time. It also tells about evaporating and canning when there is a glut in the market. It discusses fruit packages and commission dealers, and even takes in cold storage. It is a new book of 250 pages, full of illustrations. Publisher's price, \$1.00. |                         |
| Farming with Green Manures, postpaid**.....                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | 90                      |
| This book was written several years ago; but since competent labor has got to be so expensive, and hard to get, many farmers are beginning to find they can turn under various green crops cheaper than to buy stable manure, and haul and spread it—cheaper, in fact, than they can buy fertilizers. This book mentions almost all plants used for plowing under, and gives the value compared with stable manure. Some of the claims seem extravagant, but we are at present getting good crops, and keeping up the fertility, by a similar treatment, on our ten-acre farm.                                                                                                                                                                  |                         |

| While "Gardening for Profit" is written with a view of making gardening PAY, it touches a good deal on the pleasure part, and "Gardening for Pleasure" takes up this matter of beautifying your homes and improving your grounds, without the special point in view of making money out of it. I think most of you will need this if you get "Gardening for Profit." This work has 246 pages and 134 illustrations. (Retail price \$2.00.)                                                                                                                                                                                                                                                                                                      |                         |
| 12   Gardening for Profit**.....                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 1 10                    |
| This is a late revision of Peter Henderson's celebrated work. Nothing that has ever before been put in print has done so much toward making market-gardening a science and a fascinating industry. Peter Henderson stands at the head, without question, although we have many other books on these rural employments. If you can get but one book, let it be the above. It has 376 pages and 138 cuts. (Retail price \$2.00.)                                                                                                                                                                                                                                                                                                                  |                         |
| 8   Gardening for Young and Old, Harris**.....                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | 90                      |
| This is Joseph Harris' best and happiest effort. Although it goes over the same ground occupied by Peter Henderson, it particularly emphasizes thorough cultivation of the soil in preparing your ground; and this matter of adapting it to young people as well as old is brought out in a most happy vein. If your children have any sort of fancy for gardening it will pay you to make them a present of this book. It has 187 pages and 46 engravings.                                                                                                                                                                                                                                                                                     |                         |
| 3   Grasses and Clovers, with Notes on Forage Plants.....                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 20                      |
| This is by Henry A. Dreer, author of the book "Vegetables Under Glass" that has had such a large sale of late. This little book tells how six tons of grass has been grown to the acre, and gives much other valuable matter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                         |

Postage.] [Price without postage.

10 | Greenhouse Construction, by Prof. Taft\*\* ..... 1 15  
This book is of recent publication, and is as full and complete in regard to the building of all glass structures as is the next book in regard to their management. Any one who builds even a small structure for plant-growing under glass will save the value of the book by reading it carefully.

12 | Greenhouse Management, by Prof. Taft\*\*..... 1 15  
This book is a companion to Greenhouse Construction. It is clear up to the times, contains 400 pages and a great lot of beautiful half-tone engravings. A large part of it is devoted to growing vegetables under glass, especially Grand Rapids lettuce, as well as fruits and flowers. The publisher's price is \$1.50; but as we bought quite a lot of them we can make a special price as above.

5 | Gregory on Cabbages, paper\* ..... 20  
5 | Gregory on Squashes, paper\*..... 20  
5 | Gregory on Onions, paper\*..... 20

The above three books, by our friend Gregory, are all valuable. The book on squashes especially is good reading for almost anybody, whether they raise squashes or not. It strikes at the very foundation of success in almost any kind of business.

| Handbook for Lumbermen..... 05  
5 | Home Pork-making; 125 pages, illustrated..... 40  
I think it will pay well for everybody who keeps a pig to have this book. It tells all about the care of the pig, with lots of pictures describing cheap pens, appliances, all about butchering, the latest and most approved short cuts; all about making the pickle, barreling the meat, fixing a smoke-house (from the cheapest barrel up to the most approved arrangement); all about pig-troughs; how to keep them clean with little labor; recipes for cooking pork in every imaginable way, etc. Publisher's price is 50 cents, ours as above.

15 | How to Make the Garden Pay\*\*..... 1 35  
By T. Greiner. Those who are interested in hotbeds, cold-frames, cold green-houses, hothouses, or glass structures of any kind for the growth of plants, can not afford to be without the book. Publisher's price \$2.00.

| How we Made the Old Farm Pay—A Fruit-book, Green ..... 10

10 | Irrigation for the Farm, Garden, and Orchard\* 85  
By Stewart. This book, so far as I am informed, is almost the only work on this matter that is attracting so much interest, especially recently. Using water from springs, brooks, or windmills to take the place of rain, during our great drouths, is the great problem before us at the present day. The book has 274 pages and 142 cuts.

3 | Maple Sugar and the Sugar-bush\*\*..... 25  
5 | Manure; How to Make and How to Use Them; in paper covers..... 30  
6 | The same in cloth covers..... 65  
Nut Culturist, postpaid..... 1 25

3 | Onions for Profit\*\*..... 40  
Fully up to the times, and includes both the old onion culture and the new method. The book is fully illustrated, and written with all the enthusiasm and even if one is not particularly interested in the business, almost any person who picks up Greiner's books will like to read them through.

10 | Our Farming, by T. B. Terry\*\*..... 75  
Same, paper cover, postpaid..... 50  
In which he tells "how we have made a run-down farm bring both profit and pleasure."  
If ordered by express or freight with other goods, 10c less.

8 | Practical Floriculture, Henderson.\*..... 1 10  
10 | Profits in Poultry.\* ..... 1 00  
10 | Small-Fruit Culturist, Fuller ..... 75  
2 | Sorghum, Stock Beets, Strawberries, and Cement Floors. By Waldo F. Brown..... 08

This little book ought to be worth its cost for what is said on each of the four different subjects; and the chapter on cement floors may be worth many dollars to anybody who has to use cement for floors, walks, or any thing else. In fact, if you follow the exceedingly plain directions you may save several dollars on one single job; and not only that, get a better cement floor than the average mason will make.

2 | Sweet Potatoes; Forty Years' Experience with. By Waldo F. Brown \*. 08  
This little book, by a veteran teacher at our farm

Postage.] [Price without postage.

ers' institutes, ought to be worth many times the price to everybody who grows even a few sweet potatoes in the garden. It also gives full particulars in regard to handling and keeping this potato, which is difficult to keep unless you know just how.

10 | Talks on Manures\* ..... 1 35  
By Joseph Harris. Written conversational style, which makes it very interesting reading. It covers the subject very completely; contains numerous analyses of manures and comparative tables. The use of technical language is avoided, which makes the book of greatest value to the practical farmer. A book of 366 pages, nicely bound in cloth.

5 | The New Rhubarb Culture\*\*..... 40  
Whenever apples are worth a dollar a bushel or more, winter-grown rhubarb should pay big. It does not require an expensive house nor costly appliances. Any sort of cellar where it will not freeze is all right for it; and the small amount of heat necessary to force the rhubarb costs very little. The book is nicely bound in cloth, full of illustrations, mostly photos from real work, 130 pages. Every market-gardener should have this book, for the lessons taught indirectly, in regard to forcing other crops besides rhubarb. Publisher's price 50c.

5 | Tile Drainage, by W. I. Chamberlain..... 35  
Fully illustrated, containing every thing of importance clear up to the present date.

The single chapter on digging ditches, with the illustrations given by Prof. Chamberlain, should alone make the book worth what it costs, to every one who has occasion to lay ten rods or more of tile. There is as much science in digging as in doing almost any thing else; and by following the plan directed in the book, one man will often do as much as two men without this knowledge.

5 | Tomato Culture ..... 35  
In three parts. Part first.—By J. W. Day, of Crystal Springs, Miss., treats of tomato culture in the South, with some remarks by A. I. Root, adapting it to the North. Part second.—By D. Cummins, of Conneaut, O., treats of tomato culture especially for canning-factories. Part third.—By A. I. Root, treats of plant-growing for market, and high-pressure gardening in general.

3 | Vegetables under Glass, by H. A. Dreer\*\*..... 20  
3 | Vegetables in the Open Air\*..... 20

This is a sort of companion book to the one above. Both books are most fully illustrated, and are exceedingly valuable, especially at the very low price at which they are sold. The author, H. A. Dreer, has a greenhouse of his own that covers one solid acre, and he is pretty well conversant with all the arrangements and plans for protecting stuff from the weather, and afterward handling to the best advantage when the weather will permit out of doors.

3 | Winter Care of Horses and Cattle..... 25  
This is friend Terry's second book in regard to farm matters; but it is so intimately connected with his potato-book that it reads almost like a sequel to it. If you have only a horse or a cow, I think it will pay you to invest in a book. It has 44 pages and 4 cuts.

3 | Wood's Common Objects for the Microscope\*\*..... 47  
8 | What to Do, and How to be Happy while Doing It..... 65

The above book, by A. I. Root, is a compilation of papers published in *Gleanings in Bee Culture*, in 1886, '7, and '8. It is intended to solve the problem of finding occupation for those scattered over our land out of employment. The suggestions are principally about finding employment about your own homes. The book is mainly upon market-gardening, fruit-culture, poultry-raising, etc. Illustrated, 188 pages, cloth.

8 | Same, paper covers..... 40

# THE "SHELTERTOP" BUGGY

COMFORT in a buggy means something more than plenty of room and easy springs. In the "Sheltertop" Buggy it means these and several other things of greater importance. It means instant and complete protection in case of storm. It means protection from wind, dust, rain, mud, snow and cold. It means the easiest riding buggy built—the only **real** buggy improvement in a whole century. Let us tell you all about it before you buy a buggy. Our catalog describes it in detail. Write for it today, and be sure to ask for price and **30-day free trial plan**.

# Cleanings in Bee Culture

## O Errant Bee!

---

Thou art so gay, so bright and free,  
O errant Bee!  
Sipping the sweets from flower to flower  
So recklessly!  
Could I but join thee in thy flight  
And hie away  
From cares that vex and griefs that cling,  
For just one day!  
Could I but beat the air with wings  
As light as thine—  
Upon the sweets of life, like thee,  
At will could dine—  
Then, gorged with honey, hie me home  
To sleep, care free,  
And awake, unknowing what morn had  
In store for me!

Ah! is it knowledge that doth breed  
Inward unrest?  
Doth take from common daily toil  
Its welcome zest?  
O Nectar Gatherer, must we,  
For wings, forego  
The thrill which loving, human hearts  
Alone can know?  
Then hie thee to the clover-blooms,  
O Light of Wing!  
Since neither pain nor loss of love  
To thee can bring  
Heartache or sorrow—live thy life  
Griefless, care free—  
Pain is my legacy from love,  
O errant Bee!

—HELEN M. RICHARDSON, in *Farm Journal*.

## THE SPIRIT OF "THE GUIDE TO NATURE."

It is the mission of "The Guide to Nature" to draw the reader toward an appreciation of the beauty and value of natural objects and away from artificial objects to the domain of wild nature; to arouse the listless student to activity and zeal in the study of nature.

Even to the most enthusiastic of us who study and love nature, there come times when, after we have "wandered away and away with Nature," we can sympathize with what Longfellow said of Agassiz, that

. . . "the way seemed long  
Or his heart began to fail."

It is at such times that "The Guide" will inspire to greater efforts and encourage every student by telling of the faithfulness, zeal, and success of others. We all need good cheer from fellow-workers. Much of our inspiration is, "Omne vivum ex vivo," which freely translated means, "We are inspired and cheered by a friend." "The Guide" will be a leading, enticing, cheering, encouraging friend to students and lovers of nature.

The manufacturers of a certain "talking machine" advertise extensively that it "saves theater money." The publishers of "The Guide to Nature" can excel that by at least one point, and may well advertise that it "saves theater desire"—makes the theater expense wholly uncalled for, and that, too, in the best way, not in substitute on a small scale, but an excelling on a larger and better point of view.

There is no entertainment, no interest, no education, no resource equal to nature when rightly viewed. "The Guide to Nature" directs you to that view.

You who find entertainment and interest in honey-bees need no further argument. You are of the right mental make-up to understand all I would say if I wrote volumes on nature as a recreation. All you need to do is to send \$1.50 for a year, or 15c for a single copy.

EDWARD F. BIGELOW, Editor of "Guide to Nature,"  
Stamford, Connecticut.

## Honey Markets.

The prices listed below are intended to represent, as nearly as possible, the average market prices at which honey and beeswax are selling at the time of the report in the city mentioned. Unless otherwise stated, this is the price at which sales are being made by commission merchants or by producers direct to the retail merchant. When sales are made by commission merchants, the usual commission (from five to ten per cent), cartage, and freight will be deducted, and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage, and other charges, are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

### EASTERN GRADING-RULES FOR COMB HONEY.

**FANCY.**—All sections well filled, combs straight, firmly at tached to all four sides, the combs unsoiled by travel-stain or otherwise; all the cells sealed except an occasional one, the outside surface of the wood well scraped of propolis.

**No. 1.**—All sections well filled except the row of cells next to the wood; combs straight; one-eighth part of comb surface soiled, or the entire surface slightly soiled; the outside surface of the wood well scraped of propolis.

**No. 1.**—All sections well filled except the row of cells next to the wood; combs comparatively even; one-eighth part of comb surface soiled, or the entire surface slightly soiled.

**No. 2.**—Three-fourths of the total surface must be filled and sealed.

**No. 3.**—Must weigh at least half as much as a full-weight section.

In addition to this the honey is to be classified according to color, using the terms white, amber, and dark; that is, there will be "Fancy White," "No. 1 Dark," etc.

### NEW COMB-HONEY GRADING-RULES ADOPTED BY THE COLORADO STATE BEE-KEEPERS' ASSOCIATION.

**No. 1 WHITE.**—Sections to be well filled and evenly capped except the outside row, next to the wood; honey white or slightly amber, comb and cappings white, and not projecting beyond the wood; wood to be well cleaned; cases of separated honey to average 21 pounds net per case of 24 sections, no section in this grade to weigh less than 13½ ounces.

Cases of half-separated honey to average not less than 22 pounds net per case of 24 sections.

Cases of unseparated honey to average not less than 23 pounds net per case of 24 sections.

**No. 1 LIGHT AMBER.**—Sections to be well filled and evenly capped, except the outside row, next to the wood; honey white or light amber; comb and cappings from white to off color, but not dark; comb not projecting beyond the wood; wood to be well cleaned.

Cases of separated honey to average 21 pounds net per case of 24 sections; no section in this grade to weigh less than 13½ ounces.

Cases of half-separated honey to average not less than 22 pounds net per case of 24 sections.

Cases of unseparated honey to average not less than 23 pounds net per case of 24 sections.

**No. 2.**—This includes all white honey, and amber honey not included in the above grades; sections to be fairly well filled and capped, no more than 25 uncapped cells, exclusive of outside row, permitted in this grade; wood to be well cleaned, no section in this grade to weigh less than 12 ounces.

Cases of separated honey to average not less than 19 pounds net.

Cases of half-separated honey to average not less than 20 lbs. net per case of 24 sections.

Cases of unseparated honey to average not less than 21 lbs. net per case of 24 sections.

**INDIANAPOLIS.**—Jobbers are fairly well stocked, but very little honey is being offered by producers. Best grade of extracted honey is in good demand, but comb honey is finding slow sale. Jobbers are offering the following prices, delivered here: No. 1 and fancy comb, 15 to 17; extracted white clover, 8 to 9; amber, in barrels, 6 to 6½. Beeswax, 28 cts. cash or 30 in exchange for merchandise. **WALTER S. POWDER,**  
May 16. Indianapolis, Ind.

**PHILADELPHIA.**—The call for both comb and extracted honey has fallen off considerably in the last two weeks. Quite a few job lots on the market, which parties will sell at almost any reasonable offer. This makes the prices very unsteady. We quote: Fancy white comb honey, 17 to 18; No. 1, 15 to 16; amber, 13 to 14; extracted honey, fancy white, 8 to 9; amber, 6 to 7. We do not handle on commission. **Wm. A. SELSER,**  
April 24. 10 Vine St., Philadelphia, Pa.

**LIVERPOOL.**—The market for honey and beeswax is steady and quiet. We quote honey, Chilian, 4 to 6½ cents; Peruvian, 3½ to 5½; California, 7½ to 9; Jamaican, 4 to 5½; Haiti, 6½ to 6¾. Beeswax is very firm—African, 30 to 32; American, 30 to 33; West Indian, 29 to 32; Chilian, 30 to 36; Jamaican, 34 to 35.

May 13.

**TAYLOR & CO.,**  
7 Tithebarn St., Liverpool.

**SAN FRANCISCO.**—The market is almost bare of first-class old-crop offerings of comb honey, and the little that has been gathered of the new crop does not appear in this market. We quote: Comb, water-white, 16 to 17; white, 15; water-white, extracted, 8 to 8½; light amber, 7 to 7½; dark amber and candied, 5½ to 5¾.—*Pacific Rural Press*, May 16.

**ST. LOUIS.**—The honey market is very quiet. There is absolutely no demand for comb honey. Extracted honey is also neglected, consequently the prices have declined. Quote as follows: Fancy white comb honey, 15 to 16; No. 1, white and amber, 12 to 14; broken and defective, less. Extracted white, in cans, nominal at 8 to 8½; amber, 7 to 7½; in barrels, 5½ to 6; granulated extracted honey sells at less. Beeswax, 29 for prime; impure and inferior, less. **R. HARTMANN PRODUCE CO.,**  
May 11. St. Louis, Mo.

**ZANESVILLE.**—So light is the demand for honey at the present time that it is almost useless to quote the market. Stocks are pretty well reduced, and there is a tendency to cut prices, especially on the part of one-horse dealers. While the remnant of last year's crop is moving very slowly, some revival is anticipated with the arrival of the new crop. For good quality beeswax I offer 30 cts. in exchange for bee-supplies. Wax wholesalers at 40 to 45.

May 18.

**EDMUND W. PEIRCE,**  
Zanesville, O.

**BUFFALO.**—There has been no change in the price of honey since last quoted. The demand is fair for pure white comb and good No. 1 buckwheat comb. We think that about all the honey in the market will be cleaned up before the new crop is ready.

May 11.

**W. C. TOWNSEND,**  
Buffalo, N. Y.

**CINCINNATI.**—The market on extracted honey is light. We quote light amber in barrels at 6½; California white sage, 9½; practically no demand for comb honey. Beeswax sells at 33.

May 23.

**C. H. W. WEBER,**  
Cincinnati, O.

**KANSAS CITY.**—We have nothing to quote in the way of comb honey; but we quote extracted white at 7½. Beeswax, 25 to 27.

May 9.

**C. C. CLEMONS & CO.,**  
Kansas City, Mo.

**CHICAGO.**—The honey market is without volume—no special change in price of either comb or extracted. Much of the extracted from Utah will be unsold when this year's crop is harvested unless it is sold to bakers. Beeswax is steady at 30.

May 9.

**R. A. BURNETT & CO.,**  
Chicago, Ill.

**SCHENECTADY.**—We have had a few calls for dark extracted honey from manufacturers, but did not have any stock on hand. Of course, they will not pay fancy prices. Nothing is doing in comb honey.

May 9.

**CHAS. MACCULLOCH,**  
Schenectady, N. Y.

**BOSTON.**—White comb honey, fancy, 17; No. 1 white comb honey, 16; white extracted honey, 10; light amber, 9; amber, 8.

April 10.

**BLAKE-LEE CO.,**  
134 State St., Boston, Mass.

**ST. PAUL.**—Receipts are very light; demand moderate and prices steady. The prices below represent those obtained for shipment in small lots: Fancy white-clover comb, new, per lb., 18; fancy California, 24 combs per case, \$4.00; strained, in 60-lb. cans, per lb., 10. **W. H. PATTON, Sec. Board of Trade,**  
April 22. St. Paul, Minn.

**DENVER.**—The market on comb honey is slow, and prices are declining. We quote to our trade, No. 1 white, per case of 24 sections, \$3.00; No. 1 light amber, \$2.85; No. 2, \$2.70; extracted, white, 8 to 9; light amber, strained, 6½ to 7. We pay 25 cts. for clean yellow beeswax delivered here.

April 22.

(ALL RIGHTS RESERVED)

**MUTH IDEAL BEE-VEIL.**

GREENVILLE, MISS., May 1, 1908.

In regard to your Ideal Bee-veil, must say it is admirable as a protector from bee-stings, and a perfect ventilator. Could not do without it.

Yours truly,

O. M. BLANTON.

## Who Knows Best the Value, Convenience, and True Worth of a Muth Ideal Bee-veil?

### THE MAN WHO WEARS THE VEIL!

It is the neatest, quickest-adjusted profanity-preventing bee-veil ever placed on the market. It makes good every minute of every hour of every day it is worn; and it hasn't any rival within hearing distance. That's the undiluted truth!

There's about four dollars' worth of comfort and convenience packed into this strong, simple, 75-cent veil. That's all you pay for it—and we furnish postage too. We're selling them by the hundreds, day in and day out. The fine wire netting—you can smoke with the veil on—and the bee-proof apron tying tight about the body, above the waist, makes the

**MUTH BEE-VEIL BETTER THAN THE REST.**

Tried the rest? Why not try the best?

# GLEANINGS IN BEE CULTURE

Established  
1873.  
Circulation  
32,000.  
72 pages.  
Semi-  
monthly.

Devoted to Bees, Honey, and Home Interests.

Published by THE A. I. ROOT CO., Medina, Ohio.

J. T. CALVERT, Business Manager.

\$1 per year.  
When paid  
in advance:  
2 years, \$1.50.  
3 years, \$2.00.  
5 years, \$3.00.

POSTAGE IS PREPAID by the publishers for all subscriptions in the United States, Hawaiian Islands, Philippine Islands, Guam, Porto Rico, Tutuila, Samoa, Shanghai, Canal Zone, Cuba, and Mexico. Canadian postage is 30c per year. For all other countries in the Postal Union add 60 cents per year postage.

CHANGE OF ADDRESS. When a change of address is ordered, both the new and the old address must be given. The notice should be sent two weeks before the change is to take effect.

DISCONTINUANCES. The journal is sent until orders are received for its discontinuance. We give notice just before the subscription expires, and further notice if the first is not heeded. Any subscriber whose subscription has expired, wishing his journal discontinued, will please drop us a card at once; otherwise we shall assume that he wishes his journal continued, and will pay for it soon. Any one who does not like this plan may have it stopped after the time paid for it by making his request when ordering.

HOW TO REMIT. Remittances should be sent by Draft on New York, Express-order or Money-order, payable to order of The A. I. Root Company, Medina, Ohio. Currency should be sent by Registered Letter.

AGENTS. Representatives are wanted in every city and town in the country. A liberal commission will be paid to such as engage with us. References required.

## Foreign Subscription Agents.

Foreign subscribers can save time and annoyance by placing their orders for GLEANINGS with any of the following authorized agents, at the prices shown:

PARIS, FRANCE. E. BONDONNEAU, 142 Faubourg St. Denis. *Per year, postpaid, 7½ fr.*

GOODNA, QUEENSLAND. H. L. JONES. Any Australian subscriber can order of Mr. Jones. *Per year, postpaid, 6/.*

DUNEDIN, NEW ZEALAND. ALLIANCE BOX CO., 24 Castle St. *Per year, postpaid, 6/.*

# The Hand System

TO satisfy a number of customers we are now making hives to suit the above system, just as the inventor himself uses them. These are not listed in our regular spring catalog, and are not kept in stock at any of our agencies. All orders will be filled from Medina. If ordered early enough, however, they can be forwarded to any one of our branches for redistribution. If you are going to try a few of these hives the coming season, we earnestly urge you to order early before the rush season comes on.

## PRICE LIST OF HAND DIVISIONAL HIVE AND PARTS.

We have had numerous calls for divisional hives just as Mr. Hand uses them. We will not list them in our catalog for the coming season, but will make them up to supply on special order, to those who desire to try them, at prices in table below. The outside dimensions being nearly the same as the regular Dorettailed hive, the regular covers and bottoms may be used.

| Each section is 19½ in. long, 5½ in. deep outside; upper portion of side removable with clamps to hold it in place. Sections used are 4¼x4¼x1½ plain, split three sides. Furnished in both eight and ten frame size. | Designating or Short Name | Nailed and Painted Each | In Flat |         |             |

### RIDPATH'S HISTORY OF THE WORLD.

Most people who like to read at all are pleased with a well-written history. It is, therefore, a pleasure for us to state that a famous historical work, "Ridpath's History of the World," is within the grasp of all readers of GLEANINGS, even those of somewhat limited means (see page 723 of this issue). Our idea is, a good many will avail themselves of the offer made by the Western Newspaper Association, even in these somewhat panicky times, and in a presidential year when political news is at a premium. Rural dwellers where books are scarce will find this set a perfect storehouse of historical information. Many a leisure hour may be profitably spent in reading them; and one who reads with care will soon possess the foundation of a liberal education at a very small cost. Any one who reads this work might pass for a person of superior education. Ridpath's is a history of great value, well written and easily understood. Nothing will more quickly broaden a man's or woman's intellect than a careful study of history, more especially world history. He or she is bound to study geography, ancient or modern, and in this way they become sympathetic with all that goes on all over the world.

### ELECTRIC HANDY WAGON.

There are few more useful things on a farm than a Handy wagon. It will stand an immense amount of wear and tear under very trying conditions; besides, it is easy to load and unload as compared with a high wagon. One of the pioneers in this line of manufacture is the Electric Wheel Co., of Quincy, Ill., doing an immense business in constructing wagons and wheels, and whose advertising has appeared in these columns for a long time without a word of complaint. They make a specialty of supplying wheels to farmers and others who desire to change over their high wagons to low-down. Being all steel these wheels are much more satisfactory than wooden ones, and it would pay many to change on account of the saving in repair-bills. Steel wheels will last a lifetime, and give the greatest of satisfaction all the while. Many steel-wheeled wagons are in use in tropical countries with a heavy rainfall, where wooden ones do not last long, and many are in use in dry arid countries such as Mexico and Egypt, and in both cases the electric steel wheel is a winner. They are made of enormous strength, so that one may literally move a house on a set of them, and, as a matter of fact, traveling houses for lodging men and other purposes do use them. To many of our readers who are users of wagons we can not do better than to ask them to write to the Electric Wheel Co., box 95, Quincy, Ill., asking for further particulars.

## BANKING BY MAIL

**4 Per Cent INTEREST**  
Compounded Twice a Year.

Assets of over one-half million and the management of prudent men of solid financial standing give this bank every element of safety.

Send to-day for particulars, explaining how you can open an account safely and conveniently by mail.

Under ordinary circumstances all or any part of your deposits may be withdrawn at will.

WRITE FOR THE BOOKLET TO-DAY.

**THE SAVINGS DEPOSIT BANK COMPANY**

MEDINA, OHIO

A. I. ROOT, Vice-pres.

E. B. SPITZER, Cashier.

# “Please Rush My Order.”

The demand for goods following the cold period of early May will undoubtedly be very great. Orders will come to us with “Please rush” and “Ship immediately” following them.

## And we are going to do it.

We have four great railroad systems and three express companies to help us. They reach out in every direction. We also have the goods, an immense stock, and all “Root Quality.” Send for catalog.

**M. H. HUNT & SON,**  
LANSING, . . . MICHIGAN.

## Extracted Honey Wanted

We are always in the  
market.

If you have any to sell, mail  
small average sample to

**NATIONAL  
BISCUIT COMPANY**

Purchasing Department.

Washington Blvd. & Morgan St.  
CHICAGO, ILL.

## HONEY WANTED.

Wanted to contract for 20 000 lbs. comb honey in shallow extracting-frames 5% inches deep.

Requirements: Honey to be produced on full sheets of extra-thin super foundation, in shallow extracting-frames, not wired.

Grade: Same as first three grades in GLEANINGS grading-rules—Fancy, A No. 1, and No. 1 (all included as one grade).

Quality: Honey must be produced from clover, basswood, or raspberry.

Combs must be even and of uniform thickness—not over one inch.

Will furnish frames, shipping-cases, and carriers for re-shipping the honey.

Bee-keepers in Michigan or Ohio interested in this proposition, write, stating approximate number of frames you can furnish, and price wanted for the honey per pound, *net weight*, F. O. B. Medina.

Address

HONEY BUYER,

c-o GLEANINGS IN BEE CULTURE,  
Medina, Ohio.

WE WILL BUY AND SELL

## HONEY

of the different grades and kinds.

If you have any to dispose of, or if you intend to buy, correspond with us.

We are always in the market for WAX at highest market prices.

**HILDRETH & SEGELKEN,**

265-267 Greenwich St. 82-86 Murray St.  
NEW YORK.

### NEW YORK HONEY-BUYERS.

We wish to speak a word in season in behalf of an old reliable honey-buying firm which we have known for a good many years, but which our more recent readers may not be acquainted with. We refer to the house of Hildreth & Segelken, 82 to 86 Murray St., New York, who have been buying and selling honey for a generation. They make a specialty of table honey for bottling, and sell large amounts of clover, tupelo, California sage, and other nice honeys, to the grocery trade. Being situated right in the largest honey-buying center in the world they are able to dispose of large quantities. New York is accessible to honey-shippers in all parts of the country and to the West Indies, Mexico, and South America.

### WHERE SHALL WE SELL HONEY?

Many of our readers are nonplused when they attempt to sell their honey if it happens to be a little off-grade or of a kind that is not much esteemed in the local market. It is, therefore, a pleasure for us to say we have had advertising with us the National Biscuit Co., of Chicago, for some time, which is always ready to purchase just such honey at market prices. Many of our Southern friends who live far from the large manufacturing cities would find Chicago a more reliable and a more prompt market than one much nearer, but a slow buyer at low prices. We therefore cordially advise those of our readers who have any difficulty in disposing of their honey to correspond with the National Biscuit Co. You will find the complete address in their advertisement on page 673 of this issue. It is almost unnecessary to say that, financially, they are all "O. K."

### THE UNIVERSITY OF MICHIGAN.

Any young man or woman who contemplates a professional career may be interested in the advertisement of the medical department of the University of Michigan at Ann Arbor. It will be found on page 712 of this issue. Some of our readers may not know that this university has enrolled in all its departments nearly 6000 students. The course of instruction is of the best, and its graduates occupy high positions all over this country. The medical school is presided over by Professor W. B. Hinsdale, M. D., a medical man of national reputation. The University of Michigan is famous for its kindly treatment of poor students making their way against odds, and, as a matter of fact, it is not a place for rich men's sons with plenty of

spending money and little desire to educate themselves. For the farmer's boy it is ideal.

### THE BEST LIGHT.

We do not know of any thing that adds more to the attractiveness of a modern home than a first-class light in every room. It makes day out of night, and adds very materially to the comfort of the inmates by allowing them to use the evening hours for work, reading, and recreation. Many imagine it is only the city folks who can enjoy such advantages; but as a matter of fact the rural dweller can enjoy them equally well as the citizen. Many do. The Best Light Co., of Canton, O., has solved the problem by their great lamps advertised in another column in this issue. One of these in any ordinary room will fill it with an effulgence that is elevating and cheerful. It should not be forgotten that they are not expensive, either to buy or to operate. They do not cost any more than an ordinary lamp, and are actually cheaper to maintain than kerosene lights. Write and see.

### NOTICE TO QUEEN-BUYERS.

Several queen-breeders have written to say they are having trouble with some of their customers who seem to be in doubt as to what constitutes an untested queen. They somehow or other have obtained the idea that an untested queen is a virgin. This is not the case. An untested is a laying queen whose progeny have not been observed to see if they are pure-bred. Generally they are purely mated, but sometimes not, in which case the workers will be hybrids. A tested queen is one whose progeny are pure-bred, both worker and drone. An untested queen may have pure drones, and yet the workers from her are mixed. Unmated queens are seldom sent out.

### BANKING MONEY BY MAIL.

Perhaps some of our readers may not be aware of the fact that the Savings Deposit Bank Company, which is one of our steady advertisers, does a business which extends from the Atlantic to the Pacific. It does not do a vast business like a city bank, but many prefer it because it is more secure. Country banks are safer because stocks and bonds fluctuate very much in value. If your local bank is not very secure, or does not pay a fair interest on deposits, we think you can not do better than to correspond with the officers of the Savings Deposit Bank Company. They pay a very liberal rate on all deposits.

# LISTEN!

## DO YOU HEAR THOSE BEES WORKING?

Soon they will want room or will swarm.

Have you gotten your hives and supplies? If not, send your order at once. If you have The A. I. Root Co.'s catalog you can order from it. We sell their goods at their factory prices. We can fill your orders promptly now. Write for further information and our 40-page catalog.

JOHN NEBEL & SON SUPPLY CO., HIGH HILL, MONTG. CO., MISSOURI.

producers.

## Successful Co-operation

means to the Bee-keeper:—The buying of the best Bee-supplies obtainable at the closest prices, and marketing of his products to the best advantage. Our association is co-operative, and organized for this purpose. We carry a large stock of high-grade goods such as:

G.B.Lewis Co.'s      Root's      Dadant's  
Hives and Sections      Smokers and Extractors      Comb Foundation

Send to-day for our free 48-page Illustrated Catalog.

**The Colorado Honey-Producers' Ass'n**  
1440-1444 Market Street      ..      ..      Denver, Colorado

## BEE KEEPING will be a profitable industry this season.

Honey is high—short crop last year. The shortage of the honey crop for 1907 in the United States warrants bee-keepers to increase their colonies. About a half crop was produced, and in California, where the cheap honey comes from, only a quarter of the average crop was produced.

## Get Ready Now for More Honey

Let us send you our catalog. We are manufacturers and sell only our own make of bee-supplies. Minneapolis is the largest lumber-distributing point; the Mississippi river furnishes us power, and our organization and labor conditions are the best for economical production. Send us an estimate of your requirements and let us give you prices. We have a large stock of standard bee-supplies on hand.

Dovetailed Hives, Sections, Section-holders, Separators, Brood-frames, Comb Foundation, Smokers, Extractors, Shipping-cases, etc.

MINNESOTA BEE SUPPLY COMPANY, 23 Nicollet Island, Minneapolis, Minn.

## TO THE BEE-KEEPERS of CANADA.

WE are pleased to say that we are able to offer, in Canada, goods manufactured by The A. I. Root Co. While we do not offer every thing listed in their catalog, we have selected such articles as we believe will best meet the wants of the Canadian bee-keepers.

The heavy duty and freight charges we have to pay make it impossible for us to sell in Canada at Root's prices. We have, however, made prices as low as possible, and in no case do we charge nearly as much extra as the amount of freight and duty we ourselves have to pay on the goods.

We would ask you, when comparing our prices with those of other dealers, to take into consideration the QUALITY. If you do so we feel satisfied that you will place your order with us. The splendid quality of the material sent out by The A. I. Root Co. has given "Root's Goods" a world-wide reputation. Remember, "The best is cheapest."

# THE JUNE REVIEW

Starts out with an article from Mr. Elias F. Coveyou, in which he tells how to get the honey off the hives in a wholesale way, yet so manages as to

## KEEP IT WARM

for extracting. He also illustrates and describes a most excellent uncapping-box, together with his eight-frame automatic extractor, driven by a gasoline-engine.

Mr. C. W. Dayton of California, takes up the matter of uncapping honey, handling it in a scientific matter, and describing three

## RADICALLY DIFFERENT STYLES.

When to hold honey for higher prices, and when it is

## BETTER TO SELL

than to wait, are vital questions, and hard to answer, but Mr. M. V. Facey, in his article this month, really furnishes the key whereby they may be solved.

Send ten cents for the June issue, and with it will be sent two other late but different issues, together with a

## SPECIAL OFFER

showing how the Review may be obtained for this year and next at a very low price. The ten cents sent may apply on the subscription, if one is sent later.

W. Z. HUTCHINSON, Flint, Mich.

## And Still They Come

The following letter from one of our customers demonstrates in his own words the satisfaction our customers receive. Remember this is only one of the many thousands we receive.

Griggs Bros., Toledo, O.:—I received the hives and supplies to-day, which is the quickest I ever got goods after ordering. They must have come over in the Knaben shoe's airship. They certainly are in fine shape—utterly impossible for any thing to have got lost.

Your shipping-clerk had them packed to perfection.

Respectfully, HUGH RICHARDSON,  
Wood Co., O.

We should be pleased to list you as one of our customers if you are not one already. Bear in mind we handle ROOT'S GOODS exclusively, not the cheap shoddy stuff which others are trying to palm off under the pretense that it's "as good as ROOT'S." Try ROOT'S and you will be convinced. TOLEDO is the place to buy; we save our customers annually thousands of dollars in FREIGHT.

A complete line of Incubators and Poultry Supplies listed in our free catalog. Send for one.

Honey and Beeswax wanted in exchange for supplies.

## Wintering Bees in Danz. Hives

FALL RIVER, MASS., April 10, 1908.

*F. Danzenbaker*:—Kindly send booklet about your smoker as per your ad. in GLEANINGS, current issue, and for which I thank you in anticipation. I had ten hives, average good, last fall; now I have five that survived, and in Danzenbaker hives, and as I write they are lugging in pollen in good shape. Yours, H. N. BRIGHTMAN,  
Fall River, Mass.

(The defunct bees were in ten-frame Langstroth.)

Pretty good! five Danz. lived, five L. died.

**F. DANZENBAKER, Patentee.**

## What's the Matter With Hilton?

### WHY!

He has got his new goods fresh from The A. I. Root factory, and his 1908 catalog, and wants you to send for one free—40 pages illustrating and describing Root's goods at Root's prices. Send him a list of what goods you want, and let him tell you how much they will cost you.

Cash or supplies for beeswax at all times.

## THE DANZENBAKER SMOKER

PAT. OCT. 3, '06, JUNE 4, '07

### GOLD MEDALS

St. Louis Exposition, 1904  
Jamestown Exposition, 1907

IS THE BEST,  
STRONGEST,  
COOLEST,  
CLEANEST,  
CHEAPEST,  
AND LARGEST  
SMOKER SOLD  
FOR A DOLLAR

The perforated side grate seen above holds a removable, metal, asbestos-backed fire shell, preventing burning the tin off the outer case, and deflects the air at right angles, preventing back draft to the valveless bellows. The air, passing to the back and over the top, cools and expels the smoke, fanning the burning fuel at top or side till all consumed, giving cool smoke for hours from one filling. It can't clog. No top-heavy cap to choke with soot: no valve to fail; no holes shedding sparks or hot ashes.

Four years' sales prove its success beyond a doubt, expensive dies making it uniformly perfect as possible to devise. We confidently guarantee full satisfaction or refund the price.

Price, \$1.00; 3 for \$2.50; by mail, add 25c. each

Send address of yourself and Bee friends for 8-page leaflet on "Smoker," and facts about Bees and Queens, 80 pages, free.

## CONFIDENCE.

*By the Bee Crank.*

Personal confidence is based, not upon a man's character, but upon his reputation, and his reputation is simply the guess of the other fellow at the character back of it.

I have been in the Bee-supply business for nineteen years. During all of that time I have never forgotten for one minute that most of the folks who deal with me are too far away to learn much about my character; but they are all close enough to form a very clear idea about my reputation. That's why I'm as particular about little things as big ones—they all have a bearing on my reputation, and my reputation is my most valuable business asset.

When you buy supplies from me you have nineteen years of reputation-building back of the smallest item. I use care in filling orders, care in checking them over to avoid mistakes, care in packing, and care in shipping. That's the way I turn

transient customers into permanent ones. They all appreciate these things, and many of them tell me so.

Just now my warerooms are full of seasonable needs for the bee-man—nice, fresh, clean new goods ready for quick delivery. I sell Root's goods at Root's prices, and have a large supply of hives, sections, foundation, smokers, and everything that is used in the bee-yard. Everything

standard size and make, and the kind that so many have striven to imitate. My catalog tells all about them. Send for it.

I need beeswax—have a market for all I can get, and will pay highest market price, cash or in exchange for supplies.

HOOSIER-ITALIAN queens now ready. Untested, 75 cts.; select untested, \$1.00.

SHAWNEETOWN, ILL., May 15, 1908.

Walter S. Pouder, Indianapolis, Ind.

Dear Sir:—The goods ordered a week ago came promptly and in good condition. The order was for a neighbor who asked me to refer him to a reliable supply-dealer, and I recommended you. He is much pleased with his goods. Truly yours, JESSE E. DAVIS.

## STRAY STRAWS

DR. C. C. MILLER

STIMULATIVE feeding in Switzerland, as here, is esteemed differently, some finding it an advantage, others a damage.—*Schweiz. Bzsg.*

AN AFTER-SWARM with a young queen issued before the prime swarm with the old queen in several cases at one of the Swiss stations.—*Annual Report*, 59.

INTERESTING to note that, in my watering-tub, the water covered by cork chips, on cool April and May days, many bees were on the cork where the sun shone, but not a bee on the shaded part.

SOME OF US who can not attend the National convention will have the sharp edge of our disappointment taken off upon learning that the report is to be taken by Geo. Angus, the man who has done such fine work taking reports at previous conventions.

G. M. DOOLITTLE, you say, p. 630, that nailed sections take "a little longer" to put together than one-piece. Don't they take several times as long? Why don't you get a good T super and have one-piece sections just as square and just as solid as nailed ones?

G. W. DEMAREE, years ago, gave a plan for extracted-honey men to prevent swarming, that is very much like the Coveyou plan, p. 640. Just before swarming time, put all brood above, leaving the queen below an excluder on foundation or empty combs. That's all.

H. M. JAMISON, p. 643, is very disrespectful to succeed with a three-inch space between top and bottom starters after my saying they would fail. But as others also succeed I must agree that I did not know as much as I thought I did. Now, what did Mr. Pryal do to his bees to make them be so naughty?

COMPARATIVE advantages of comb and extracted honey production are ably discussed in *Review* by R. L. Taylor and the editor. Both think that 50 per cent more of extracted than comb is about the fair estimate. But honey quotations in the same journal show the price for comb about 80 per cent higher than for extracted. Now, suppose my field furnishes 10,000 lbs. of comb for which I can get \$1440. If I can get 50 per cent more extracted, that will be 15,000 lbs.; but at the difference of price named it will bring me only \$1200. That difference of \$240 is not balanced by the extra expense of sections, etc. Other factors are to be considered, however, and there is no doubt that, for many, extracted is decidedly more profitable.

FICKLE though it may be to do so, I must change my mind again about strengthening a weak colony by putting over a strong one. I tried two cases this year. I used wire cloth as a precaution; but when I came to lift the upper story I found the dead queen on the excluder. Unsealed brood above showed that the queen was not killed until some time after the wire cloth was removed. [The position of the queen at the time you found her would indicate that a mortal combat had taken place *through* the perforations. Queens will sometimes grab each other in deadly embrace. At such times it is possible for one to sting the other. It is rare, however, that they fight through the perforated metal, and in the case cited, therefore, we would say that it was only an exception that proved the rule.—ED.]

SOMETHING I never noted before, I learned this year, May 1. On that date we went to the Wilson apiary and watched the bees at the entrance of each hive. If they flew strong, carrying plenty of pollen, we judged them queen-right. Several did not fly well, and we opened their hives. They were strong in brood and bees, but very light in honey. They showed no sign of starvation, having enough honey for immediate use. One would have supposed they were the very ones that should have been out and hustling; but the scarcity of stores seemed to have a depressing effect. Is it possible that abundance of stores in sight encourages them to greater activity in flight, just as it is believed to encourage them to greater activity in brood-rearing? At any rate I prefer my bees should have a goodly surplus of stores on hand at all times. [If we remember correctly, reports have shown just the very thing here described. We should be glad to hear from others on this point; for if it be true that colonies on the verge of starvation will not seek nectar from the fields when it is to be had, it goes without saying that it would be good policy to give all the colonies a liberal supply of food in the fall.—ED.]

REPLYING, Mr. Editor, to your question, page 622, as to combs melting down in hives surrounded by corn and dense underbrush, I may say I know of no other untoward condition that would cause such melting down except that overhead the shade from closely planted trees was so dense that the sun never shone on the hives all day long. The first intimation I had of any thing wrong was when I saw the little stream of honey running on the ground. At that time I did not have hive-entrances as large as now, or there might have been no trouble. But there was no trouble with hives that stood out where they had the advantage of any passing breeze. [We infer, then, that the cause of melting down was due to a combination of too much underbrush close to the hive, and too small an entrance. Without

the underbrush, and with such entrance, the combs would not have melted down, you say. We should infer that, had the entrance been larger, even with the underbrush, there would have been no trouble. If that be true, it goes to prove that, with a large entrance, and an Alley trap over it, there would be no breaking-down of the combs. In this we assume that the Alley trap would be the equivalent of the underbrush.—Ed.]

LOUIS SCHOLL, replying to your question, p. 629, I never had either of the troubles from wide bottom-bars that you mention. Before the first comb is taken out, the removal of the dummy makes sufficient room so that never do "the wide bars cause the bees to be rolled over the combs of the next frames." Perhaps you use no dummy. The bottom-bars do not "stick together" "when the frames do not hang quite true" because it never happens that the frames do not hang quite true. They are exactly spaced by nail spacers, and a nail in the end-bar,  $2\frac{1}{4}$  inches from the bottom, makes the spacing just as true at the bottom as top. Perhaps your bottom-bars are not thus spaced. I day before yesterday, May 14, owing to the rush of honey from fruit-bloom we found it necessary, at an outyard, to give extra room. In the case of some strong colonies having extra wide bottom-bars, we noticed that they were stuck together with great chunks of propolis so that it was difficult to pull the frames out; and as the frames were removed, a taffy-like glue stretched out in strong strings. This attaching, however, was only by the Caucasians and the Caucasians crossed with Italian blood; and if one were to use this race and their crosses he might be compelled to use both narrow end-bars and bottom-bars, and perhaps get along without self-spacing devices.—Ed.]

"MUCH LABOR can be saved in the critical time of the honey-flow if there is a superabundance of supers and combs," *Review*, 151. Suppose I average one year with another a surplus of two supers per colony. Will that number in readiness be a plenty? But what if an extra good year comes? Suppose the best year in the past gave me five supers to the colony. I might call that an abundance to have in readiness, but it would take about another super to be a superabundance. Yes, I believe in superabundance, and, as a matter of fact, I generally have in readiness more than six supers to the colony. If ever a bee-keeper feels like kicking himself, metaphorically speaking, it is when he has been so shortsighted as not to have a sufficient number of combs or supers ready for a good honey-flow. By the rush of orders that have been coming in, we imagine that the fruit-bloom this season took a great many by surprise. About every two or three years the supply-dealer and the manufacturer find themselves swamped with orders simply because bee-keepers do not or will not order in the fall, thus getting the benefit of a discount and the further advantage of having goods ready when needed. It may be said that the supply-dealer and manufacturer should have a large stock in readiness for rush orders. That may be true; but it would be impracticable to have warehouse capacity sufficiently large to take care of the exceptional seasons.—Ed.]

## EDITORIAL

As we go to press we are pained to learn of the death, on May 16, of Mr. D. E. Merrill, of the W. T. Falconer Mfg. Co., Jamestown, N. Y. Particulars will be given in our next issue.

MR. OREL L. HERSHISER, of 493 Woodward Ave., Buffalo, N. Y., has been recently elected to life membership in the Buffalo Society of Natural Science. This came unsought and entirely unexpected to our friend. It was due to certain lectures that he has given before that organization.

### CROP REPORTS.

If we may judge by orders that have been coming in, as well as by the work of bees in our own locality, this has been a very remarkable year for fruit-bloom honey in the northern belt of States. While this honey will not reach the market, it will be the means of putting the brood-nests in fine condition for the clover flow yet to follow. The frames will be full of brood and honey, and the new flow from clover will necessarily have to be put in the supers.

The reports from other parts of the country have been quite encouraging, as a rule. Briefly, they are as follows:

#### ALABAMA.

Prairieville.—White clover in bloom, but weather too wet and cold.

#### CALIFORNIA.

San Diego.—Not very good prospects for crop along the coast. In the mountains a good crop is expected.  
Surrez.—No honey, many bees dying.  
Ventura.—Dry weather and frost checked the growth of sage, therefore no prospect for honey.

#### CANADA.

Marchurst.—Backward spring, but prospects good for clover.

#### ILLINOIS.

Lawrenceville.—Bees swarming early.  
Royal.—Bees beginning on white clover.

#### INDIANA.

Madison.—Good prospects for a crop.  
Huntington.—Necessary to feed to prevent starving; prospects good for white and alsike clover.  
Wolcottville.—Colonies very strong.

#### IOWA.

Marshalltown.—Good rains; white clover everywhere; good prospects for a crop.  
Kalona.—Cold weather causes great loss of field bees.  
Bloomfield.—Heavy rainfall insures good white-clover bloom.

#### KENTUCKY.

Cornishville.—White clover abundant. Good prospect for crop.  
Boyd.—Honey prospects extra good. Fine crop of alsike and white clover.

#### MISSOURI.

Bluffton.—Weather wet; good prospects for clover.

#### NEBRASKA.

Bradshaw.—Bees working in supers.

#### NEW JERSEY.

Frenchtown.—Weather very unfavorable for honey and brood-rearing.

#### NEW YORK.

Middleburg.—Weather wet, but lots of brood and young bees.  
Bedford Station.—Weather cold and wet.  
North Branch.—Good prospects for a crop.

#### OHIO.

Shanesville.—Good prospects for a crop.  
Athens.—Bees swarming, and working in supers.  
Belpre.—Bees swarming, and good prospects for white clover.  
Akron.—Bees swarming very early.

#### OREGON.

Hillsboro.—Coldest spring in many years. Half the bees are dead on account of spring dwindling and starvation.

PENNSYLVANIA.  
Liverpool.—Good prospects for a crop.

TEXAS.  
Orange.—Good flow of excellent honey.

VIRGINIA.  
Lindsays.—Good prospects for a crop.  
Howardsville.—Colonies strong, but the weather is cold.

WEST VIRGINIA.  
Ravenswood.—Good prospects for a crop. Bees swarming.

#### AN INJURY TO THE EDITOR'S EYE.

E. R. ROOT will be compelled to beg the indulgence of his readers for some two or three months to come, perhaps, because of an injury to the right eye. He is under orders not to read any proof or printed matter, nor manuscript, for some months to come, and to give both eyes a rest until the injured member can recover from the shock.

As a warning to others, we would say that the injury was due to looking at a strong arc light for the fraction of a second, at too close a distance. While the injury is, to a certain extent, permanent, it probably will not entirely disqualify the right eye from service after it has been given a rest. In the mean time all manuscript is read to us, and all other matter, as heretofore, is dictated. Owing to the fact that we can not use our own eyes our subscribers are requested not to pass severe judgment in case the editor should say what he does not mean, or fail to give the exact meaning he intends to convey.

But there is no great loss without some small gain. We are privileged to go outdoors, and we are now finding recreation by working with the bees, helping the boys every now and then, for the specialist does not believe that long-range vision, provided blue glasses be used, or a hasty glance over a frame of bees, will do any harm, but we must not look for eggs.

The left eye, we are very glad to report, is entirely uninjured, and is in every way all right, but the use of it might affect the other eye.

#### CAUCASIANS EXCESSIVE BREEDERS OF DRONES ; WHAT THIS WILL MEAN.

ONE of our correspondents, Mr. C. W. Price, in this issue, in uttering words of praise for the Caucasians states one thing that is not very much in their favor; and that is, they are inclined to raise too large a number of drones. We find this to be emphatically true in one yard where we raise Caucasians. They run excessively to drones in spite of the fact that we are using full sheets of foundation. If the cells are slightly elongated, drones are sure to be reared in great numbers. If there happens to be any drone comb built to fill out space in worker comb removed it will be solid with drone brood.

So far as the loss of energy in rearing drones is concerned, that is a small matter. At a yard where we have mostly Caucasians and some Italians, the Caucasian colonies will rear a hundred drones to the Italians one. This simply means that the Caucasians will run out the Italians in very short order; for if there were a hundred Caucasian drones flying to one of Italian, the whole locality would run to the black strain of bees rather than to the yellow. If, therefore, one introduces Caucasians in his yard for the purpose of experiment he will have to put on

drone-traps and shave off the heads of the drone brood every now and then — otherwise the yard will run to Caucasians. If they should prove to be undesirable it would be unfortunate to say the least.

#### PLANNING WORK AT A BEE-YARD; EXCHANGING BROOD AND STORES.

A STRONG flow of honey was on from fruit-bloom — so strong, in fact, that we never saw as much nectar coming in, even from basswood. Colonies which, on the opening of the bloom, were on the verge of starvation, filled their hives jammed full of honey, ready for capping, in the short space of three days. Even nuclei made a wonderful showing. The question of giving room was one that required immediate attention. We had only a limited number of supers and empty combs at the yard. It was important to give relief where it was needed the most. We accordingly watched the flight of bees at the entrances of all the hives. From all those colonies where the bees were flying the strongest we removed the upper cover, leaving the thin board super-cover on top. Then we looked at the entrances of all the hives where there seemed to be the least doing, and turned their covers cat-a-cornered. This shift of covers was for the purpose of designating the hives. We then took a hasty glance into the brood-nests of every one of the hives of both the strong-working colonies and those that showed but little indication of field work. We thus found the exact condition of the strongest flyers and of the other sets. We now proceeded not only to make the strong help the weak, but the weak to help the strong. The former were made to give up their empty combs, if they had any, to the latter, exchanging unsealed brood for hatching brood. In the case of the very strong ones, where the hives were jammed full of honey, we put on supers. This done, we had the extra strong and the weakest to a certain extent equalized, the strong being given unsealed brood and empty combs from the weak, and the weak, on the other hand, being given sealed brood and combs jammed full of honey from the strong.

We now had left unexamined only the medium colonies in the yard. Some of them were not suffering for room, and when we went across them we marked them, and from those that needed room we took combs filled with stores, and exchanged them for empty or partly filled combs from the marked ones. When we got through the yard every colony had its hive filled full of honey of nearly equal amounts. The very strong ones had mainly unsealed brood, while the weak and the very weak had mainly sealed and hatching brood.

During this process of exchanging brood and stores it was necessary to keep open some seven or eight hives at a time. During all of our work the editor's eldest son was kept busy opening and closing hives, bringing back and forth combs and brood to and from the hives.

In this connection we might remark that a comparatively inexperienced man or boy can enable one good man to do almost two men's work; for the expert can furnish brains for the muscle of two men; and the result is a harmony of plan and of execution.

"NEW LIGHT ON FOUL BROOD."

IN the *British Bee Journal* for April 30 and May 1 there is a general discussion of some new investigations made by Dr. Maassen under the above caption. It probably would not be interesting to give the whole of this, but we will here give the summing-up as found in the *British Bee Journal*, pages 183 and 184.

To sum up Dr. Maassen's important work, we find: 1. That three different organisms may produce foul brood, two of which are usually associated in different phases of the disease. These are *Bacillus alvei*, Cheshire; *Bacillus Brandenburgensis*, Maassen (syn. *B. Burri*, Burri, *B. larvæ*, White); *Streptococcus apis*, Maassen (syn. *B. Guntheri*, Burri).

2. That when the disease attacks unsealed larvæ *B. alvei* is present, and in virulent cases it is also found in sealed brood.

3. That *Streptococcus apis* of "sour brood" is usually associated with *B. alvei*.

4. That *B. Brandenburgensis* is found in the sealed larva only just before it changes to a pupa, and is frequently associated with *B. alvei*.

5. That the two bacilli are antagonistic to each other, and are constantly struggling for supremacy, sometimes the one and sometimes the other getting the upper hand.

6. That other bacteria are sometimes associated with *Streptococcus apis* which kill its cocci, so that bees are able to remove the dead larvæ, and in some instances during a good honey-flow the disease may be kept in check or the colony become for a time cured.

7. That the disease in which either or both bacilli are present is equally infectious.

The editor of our esteemed contemporary seems to take the view that some of the conclusions arrived at by our own Dr. White, of the Department of Agriculture, are incorrectly drawn. We have carefully gone over this whole discussion, but we do not see that the conclusions are so widely different from those arrived at by Dr. White. Indeed, in many respects the work of the two men runs along in parallel lines.

For example, both find in the ropy type of foul brood the same bacillus, though under different names. Dr. Maassen designates it as *Bacillus Brandenburgensis*. Another name is *B. Burri*, after Burri, a bacteriologist of note, while Dr. White calls it *B. larvæ*. By whatever name it may be called, all three of the bacteriologists agree that it is one of the pathogenic microbes found in ropy foul brood. Dr. White makes no claim that it is the sole cause, while Dr. Maassen appears to share the opinion that *B. alvei* as well as *Streptococcus apis* are also present and also pathogenic—that is, they are disease-forming. There is no contradiction between them on this point.

Again, while Dr. White has found *B. alvei* in the ropy type, so far as we remember it was only in the combination of black (non-ropy) and ropy foul brood. Dr. Maassen, on the other hand, seems to hold the view that *B. alvei* and *B. Brandenburgensis* (*B. larvæ*) are both the primal causes, the one struggling against the other for supremacy, but *B. alvei* being more predominant in the unsealed stages of the dead matter, while the other seems to be more in the supremacy after the sealing.

This, in our judgment, goes a long way to confirm the statement made by Dr. White, who finds that *B. alvei* is always present in black brood which mainly manifests itself in the unsealed stage of affected brood, while *B. larvæ* is always found in ropy foul brood, which disease shows itself mostly in the sealed brood.

Again, Dr. White finds that the *B. larvæ*, *B. Brandenburgensis*, or *B. Burri*, or whatever we may call the microbe, will not grow in ordinary

beef gelatin for pure-culture work; but that it does grow in the juices of larvæ. Dr. Maassen finds a difficulty in propagating the same bacillus in beef gelatin; but, like Dr. White, he does find that it will grow in larval juices, and also in a product made from brains and albumen. Here again we have a harmony of opinion.

Dr. Maassen seems to take the view that *B. alvei* is always found in the ropy type of foul brood, while Dr. White finds it only occasionally when there is a combination of the two diseases.

It is not entirely clear to us that the black brood of Europe is the same as the foul brood of this country. The difference in environment may account for the difference in findings.

The summary of the whole matter is that Dr. Maassen believes that ropy foul brood is caused primarily by three microbes, the two most prominent being *B. alvei* and *B. Brandenburgensis*. Dr. White inclines to the view that ropy or American foul brood is caused by *B. larvæ* or, what is probably the same thing, *B. Brandenburgensis*; that *B. alvei* is not found in normal ropy foul brood, but he does find it invariably in black brood or what the Department has differentiated as "European" foul brood.

Speaking of American and European foul brood to designate respectively the old-fashioned ropy foul brood and black brood, some regard these qualifying adjectives as very unfortunate, because European foul brood is rarely found in Europe, but is very common in some portions of the United States; while American foul brood is very common in Europe as well as in America. But we regard this question of English names as unimportant. At the present time there seems to be a divergence of opinion regarding the primal causes of ropy foul brood, while Europe seems to be silent on the causes of black brood.

As the writer has been unable to go over this entire discussion on the printed page for the reasons stated elsewhere, depending on his ears only, it is possible he may not have stated correctly the views held by American and European scientists.

*Later.*—We have gone over this whole matter again; and it is increasingly evident, first, that between the bacteriologists of Europe and America there is more and more an agreement in the findings. Second, that the real black brood, such as was found in New York, apparently does not exist in Europe except in combination with the ropy type of foul brood. The descriptions of the external characteristics, so far as we have been able to find them, do not indicate a black brood such as we have in America, but a modified form. If this be true, it will be very easy to harmonize to a great extent the variations in findings of the bacteriologists. We have every reason to hope that the time will soon come when the slight confusion now existing will be cleared up.

For the benefit of our European cousins we may remark that there is a very marked difference between what we have been calling black brood and the old-fashioned ropy foul brood. The difference in the character and odor of the dead larvæ is very decided, and this is also true of the effects. It is rarely true that the one disease is supplanted by the other, or that both are in the hive at one and the same time.

## CONVERSATIONS WITH DOOLITTLE

### WAX SECRETION.

"I want to ask you a question or two, Mr. Doolittle, regarding wax secretion. It is calculated that a ten-frame Langstroth hive requires about 2 lbs. of wax to fill it with comb, is it not?"

"I think that is about the estimate, and it is not far out of the way."

"Then are you prepared to say that, when swarms are building their own comb, and filling the brood-chamber with brood and honey, other and similar swarms, which were supplied with full sets of ready-made comb, would store a surplus of 50 lbs. of honey?"

"I do not know that I fully understand what you are after; but I judge that you think the estimate of the consumption of 25 lbs. of honey to produce one pound of secreted wax is too high a figure."

"Cut it down to 25 lbs. surplus from the ready-made combs, as against nothing from those that built their own comb: what do you say now?"

"The claim put forth by some that it takes 20 lbs. of honey to cause the bees to secrete a pound of wax, and that the bees would gather 5 lbs. of honey while they were manipulating the pound of wax into comb, thus making an expenditure of 25 lbs. of honey for every pound of comb built in the hive, I have always considered a fallacy."

"Do you know upon what such calculation was based?"

"Upon Huber's experiments, I think."

"Then Huber must have been a careless experimenter."

"I should hardly want to say that. I think there is no question but that the experiments of Huber, proving that it took 20 lbs. of honey to produce one pound of clean (wax) comb were correct, under the conditions by which they were tried; but it must be remembered that bees are thrown out of their normal conditions when they are confined to their hives so that they may receive no benefit from the fields; and when not in a normal condition there is no accounting for what they will do. Most of our practical apiarists of the present time have been led to believe that the real cost in honey to produce one pound of clean comb, when the bees are in a normal condition, is from 5 to 10 lbs. This being the case, the true answer to your question would be that you should secure from 10 to 20 lbs. of honey extra from a swarm hived on a full set of combs, in a Langstroth ten-frame hive."

"Then that is as you believe?"

"From my experience covering about forty years, taking an average, this difference is about right."

"Well, you and I can not agree."

"How is that?"

"There is an important part which has not as yet been touched upon at all."

"To what do you allude?"

"To the fact that bees secrete wax during any and every heavy flow of honey, whether the hives have comb in them or not. Let me tell you

some of my experience. I have been extracting honey from a part of my colonies during the past four years; and when honey was coming in abundantly I have seen workers in extracting colonies that were laden with great pellets of wax scales sticking out on the under side of their abdomens. I have caught such bees, and with the point of my knife have pulled off these pellets of wax, piling the eight pellets together, when I had enough coming from one single bee to build a good part of one cell if not the whole of it."

"But that wax was probably to use in lengthening out the cells and capping the honey a second time, after you had shaved off the cappings and a part of the comb the time before, when extracting."

"Possibly some of it might have been used in that way. But I had not finished. At such times I have seen wax used to plaster on the front of the hive, to chink cracks, putting great knots or knobs of it here and there, where there seemed to be no purpose other than to get rid of it in some way. Aren't the bees silly to eat honey from which to make wax just to waste? If the cost of wax is 5, 10, or 20 lbs. of honey, it would seem to me the bees should know enough to store that away for future use when they have the combs all provided, rather than use honey to secrete wax when there is no comb to build."

"Then your idea is that the bees secrete wax during a heavy flow of honey, and do this without regard to whether there is any comb to be built or not."

"That is right. And I consider the filling of a hive with foundation, of combs already built, only a waste of the cost of the foundation, and the time and trouble of using it."

"And I think you are a little hasty in your conclusions. Listen a minute. There is an element which comes in right here that is well worth considering. Swarms hived in full ten-frame Langstroth hives, with empty frames, or those having only starters in them, are almost sure to put much of the wax you are talking about into drone comb, especially if the queens are not very vigorous; and this drone comb is against the best usefulness of such colonies for all time to come, so long as those combs are occupied by bees; and to do away with this drone-comb nuisance, a few combs to insert when the bees persist in building drone comb are a bonanza, even if they cost 50 lbs. of honey to build five of them."

"Why do you specify five?"

"Listen to this: Hive your swarms on five empty frames, having only starters in them, putting on a super of sections when hiving, and the bees will build out the five combs nearly if not quite all the worker size of cell, if their queen is good for any thing. Now take out your division-boards, or dummies, which have been used thus far, and fill out the hive with five nicely built worker combs, and you have things as they should be, and something which will be a pleasure to you as long as you and those combs live together."

"But you don't think all the wax will be saved in that way?"

"There will be no loss of wax when working in this way provided you have the surplus arrangement partly filled with comb foundation, as

any knobs of wax not needed below will be used in building combs in the sections. In this way we kill two birds with one stone."

## GENERAL CORRESPONDENCE

### HONEY-HOUSES.

#### A Description of Some of the Honey-Houses in Northern Michigan and an Outline of the Methods Used.

BY E. D. TOWNSEND.

As our yards are all located on rented ground, so that frequent moving is necessary, we build the honey-houses in sections. The floor is in halves; the sides and ends are separate, and bolted together with two bolts in each corner, and each side of the roof is built independently of the rest of the building so a half can be taken off at a time for moving.

A 32-inch door is put in one end, without screen or glass, for door-screens attract the robbers so that some of them are sure to dodge in when the door is opened. Centrally located on both sides of the building, next to the plate, window-holes are cut, and covered with wire screen nailed on the outside with lath strips to hold it down. These window-holes are boarded up with a framework which slides to one side to let in the light. As all the work at the outyards is done during warm weather, no glass is necessary.

The framework above is of 2x4 material, planed on all four sides, while that below the floor is 2x6, not planed. The siding is of single boards planed on both sides and nailed up and down; the roof-boards are the poorest of the same material. See GLEANINGS for Oct., 1906, page 1242.

#### TAR BUILDING-PAPER TO LINE BEE-PROOF HONEY-HOUSES.

To make our honey-houses bee-tight we have tried several kinds of building-paper, but have decided that tar paper is the best. We put it on with lath, being sure to have it lap well at the joints, and to fit the corners perfectly. Wherever there is likely to be a bee-space or opening we are especially careful. We have never yet been able to find a carpenter who would do the work well enough, and we believe that the bee-keeper should attend to the papering himself, therefore, whenever possible.

A honey-house papered April 1st will have lost most of the smell of tar by the time much work is done, so those who do not like the smell need not hesitate, for it is of short duration.

Bees, mice, and ants dislike tar paper, and hardly ever go near it. The mice never gnaw it and let in bees, as they will do if other kinds of paper are used. Some of our honey-houses have not had a mouse in since tar paper was used; but they make nests of the white building-paper we used to use, and some of the houses had to be repapered each year. The worst mistake we ever made was to paste on the paper. The mice seemed to

follow us and eat the paste as fast as we could put it on—of course, tearing the paper meanwhile. When the house is lined with tar paper we never see any ants.

#### THE CHAPMAN HONEY-HOUSES.

At his home yard Mr. Chapman has a fine new honey-house and storeroom, with his bee-cellar under it. As this is his headquarters, much of his material is kept there until wanted at the outyard. While this house has all of the latest appliances to be found in most home-yard houses, I want to talk most about the one at his outyard, which is, perhaps, ten feet square. There is room only for the operator, extractor, tanks, etc., so the team is hitched to the big wagon, and the honey-cans and such other things as will be needed for extracting are hauled to this yard in the morning. The honey is taken off the hives, extracted, strained through cheese-cloth, canned up, and set out of doors until the day's work is done, when the bees will have stopped flying. The team may then be driven to the house to get the honey, for it is drawn home each night. By this plan the honey is canned as fast as extracted, so all of the aroma and best flavor are retained. Such a plan is a very good one where the outyard is so near that the honey can be drawn home every day. Some of our own yards are worked much on the same plan, although we do not have to draw all the honey home each night, having plenty of room at the house to store it.

Mr. Chapman, not having room in the house to store the combs after extracting, sets them out for the bees to clean up immediately. A load of the wet combs just extracted is taken out to one side of the yard, and placed criss-cross for the bees to clean. The writer happened on the scene one July day when the extracting was going on; and as the flow from raspberry had ceased, there was nothing for the bees to do but to carry in this honey from combs. While there seemed to be quite an uproar, the honey was being taken without any sign of robbing.

When the season is over, as there is no place in the extracting-house to store the tools over winter they are all drawn to the main house at the home yard, as are the empty combs after they are cleaned of the honey that is left on them after extracting.

#### THE COVEYOU HONEY-HOUSE.

Mr. E. E. Coveyou, like many of the outyard bee-keepers of Michigan, uses some of the abandoned lumber-camp buildings for his honey-houses. He does not try to keep the bees from entering his honey-house, but plans to do the work at a time when the robbers are not likely to bother much. The honey is taken off the hives during the day and piled up in the yard, being covered so the bees can not get to it. Then, toward night, after the sun has warmed the honey, it is taken into the honey-house and extracted with his big eight-frame automatic extractor. It does not take long to do this, and the work is done so late in the day that the robbers do not get started much before it is too late for them to fly. After all the honey that was taken off is extracted and canned the combs are piled up and covered so the bees can not get to them. The extractor and uncapping-box are also closed beetight. This is not a very desirable way of han-

dling a crop of honey, and is the only flaw I have been able to find in Mr. Coveyou's methods. However, I understand that he will abandon this plan next season for another one which I will describe later.

#### KIRKPATRICK'S HONEY-HOUSE.

Mr. Geo. H. Kirkpatrick, Rapid City, Mich., who has several yards of bees in the raspberry region, builds all his extracting-houses small, and depends on storage room elsewhere for his honey and combs. His honey-houses differ from Mr. Chapman's in that he puts the honey he uses into a large honey-tank, instead of directly into the cans. The houses are built about 12 feet square, bee-proof, and about a third of the floor space at the back end is let down three feet lower than the main floor. In this lower part are located the tank and scales, so arranged that the honey from the extractor runs directly into the tank, and from this tank into the 60-lb. can resting on the scales. The honey is all extracted after the season closes, and is in good condition to can as soon as extracted; but it is left in this large tank over night, then skimmed and drawn from the bottom. This makes very clear nice-looking honey, and handled this way it is of good quality. While Mr. Kirkpatrick is a convert to the better way of canning the honey direct from the extractor, he has not changed his outfits yet, but probably will do so during the coming season.

#### THE HUTCHINSON HONEY-HOUSES.

The Hutchinsons have their outyards near some of the abandoned lumber-camps, so they build over the camp-buildings for a honey-house. Usually these camp-buildings are much larger than necessary, and partitions are run across to make the bee-proof honey-room. Besides the main extracting-room, there is a small room of suitable size for heating the honey before extracting. This room is lined with paper, to retain the heat from the large oil-stove used to heat the honey. The honey is taken off with escape-boards, and stored in this room where this oil-stove is lighted the night before they intend to extract, with the result that, in the morning, the honey is in much better shape than that just from the hive. Honey just from the hive, especially on cold mornings, does not extract very clean, and requires a long turn of the extractor to get it at all.

A few times I have warmed the honey to be extracted; and if things are arranged right, there is no other way that is so satisfactory. The honey is just a little warmer than that from the hive in the hottest weather, which makes it about as thin as water, and of course it is thrown out of the combs much easier, and the combs are extracted very dry.

#### EXTRACTING IN THE OPEN AIR.

At one time I worked ten swarms of bees on shares, for a neighbor, and I did the extracting out of doors under a shade-tree. Every thing was kept covered up as much as possible to prevent robbing; then a smoker was kept going, and the assistant would keep the smoke where it would do the most good. This yard of bees had not been handled, and the colonies had not learned the robbing habit, so they were not very bad to commence with.

#### THE IDEAL HONEY-HOUSE.

The ideal honey-house for a hundred-colony bee-yard would be a building 18 x 24, lathed and plastered on the inside. It should be built at the lower edge of the bee-yard, to facilitate wheeling the honey from the yard. It would be better if the gentle slope of the ground were to the south or southeast. I would build the end of the building toward the bee-yard, with a good wide door at both ends. The ground at the back should be about six feet lower than the front, to allow a platform wagon to stand with the top on a level with the honey-floor for convenience in loading and unloading honey, supplies, etc.

Two-thirds of the floor on the end toward the front or bee-yard should be built on a level with the ground at this point for convenience in wheeling in honey; then the third toward the back end would be built two or three feet lower than the front or main floor. The front floor would be for the main workroom where the extractor, uncapping-box, and combs are kept. The lower floor would be for the honey-tank, scales, honey-cans, etc., and the distance this lower floor should be below the main floor would be determined by the height of the tank to be filled; for the extractor would be set at the edge of this upper floor, with the gate projecting over so the honey could run direct from the extractor into the tank, then from the tank to the 60-lb. can on scales. The shallower the tank, the less difference there would have to be between the two floors.

Remus, Mich.

#### BEE-KEEPING AMONG THE CELTIC MONKS OF GREAT BRITAIN.

##### Why Candles of Beeswax are Used for Sacramental Purposes; a Church Built by the Bees.

BY FATHER MAURUS MASSE, O. S. B.

As in the honorable mention you make of us in the January 15th issue, page 83, you do not seem quite certain whether we read GLEANINGS and the A B C, I am penning these lines to assure you that we do read them both with great interest and pleasure. What you say of European clergymen as being often ardent disciples of the bee-keeper's art is quite true, and my researches in that line lead me to conclude that it was still more so centuries ago; for then it was not only pleasure and profit but necessity that prompted them to keep bees. To mention only the Celtic monks of Great Britain, and, later, of Armorica (whither they were driven by the Saxon invaders), for whom I may be pardoned for taking a special interest as one of their race and profession, many a quaint story is related in ancient chronicles about their apicultural successes. Thus we find the following interesting account of the exchange of their products with the Parisian abbeys:

One day St. Samson, abbot and bishop of Dol (in those times abbeys very often became bishoprics) and the bishop of Paris talked together about their monasteries. St. Samson mentioned that his monks were such good managers, and so careful of their hives, that besides the honey, of which they had an abundant supply, they had more wax

than they could use in the church during the whole year; but that the country, not being fit for the growth of vines, they had a great dearth of wines. "And we, on the contrary," said St. Germain (bishop of Paris), "have vineyards in abundance, and a much greater quantity of wine than is wanted for the supply of the monastery; but we are obliged to buy wax for the church. If it pleases you we will give you every year the tenth part of our wine and you shall furnish us with wax to light our church." Samson accepted the offer, and the two monasteries mutually accommodated each other during the life of the saints.

I have gone to some length to quote this agreement, because it illustrates very well what must have been the custom in most Celtic monasteries of that period, not excepting Buckfast Abbey, as the extant records would imply; for this old abbey had a Celtic origin, and is believed to have been founded in the sixth century by the great British saint, Petrock, son of a Welsh king. St. Samson, spoken of above, was a compatriot and an intimate friend of our founder, and on his way to Armorica came to Devonshire to spend a few days with St. Petrock, when, I feel sure, the bees formed an item of their conversation, just as it happens now when two bee-keepers meet. Another British monk of the same period (sixth century) was so celebrated as a bee-keeper that popular tradition invested him with the glory of having introduced bees into Ireland. This predilection for bees went so far that in monasteries, which, by the will of their founder, were sometimes to remain without earthly possessions, yet was there an exception made in favor of bees, of which they could have an unlimited number. This should not astonish us if we bear in mind that monks like to consider their monastery as a "Holy Land" where floweth the milk and honey of spiritual graces and consolations; and the analogy is brought home to them more forcibly by the presence and taste of the material honey. Ancient writers even compare the monastic home to the bee-hive, because, as says Virgil, "Innatus apes amor urget habendi," so "the monastery was a hive of piety and industry wherein the monks gathered in abundance the richest honey of religion, literature, and science, to be freely dispensed to those around them."

But, besides such mystical considerations, there was, as I said, the reason of necessity. You are aware, no doubt, that in the Catholic Church beeswax candles are extensively used for divine services, and their liturgical meaning is to represent Christ, the light of the world. No other material could replace beeswax, which has a noble and beautiful mystical signification; for, being produced by a virgin insect, it represents the body of Christ produced by a virgin mother; hence the great consumption made of that precious substance for church purposes. It is marvelous to read what Anglo-Saxon writers tell of the splendor of divine worship at the times when Briton and Saxon alike flocked to St. Mary's Abbey on great festivals; of the countless waxlights that made night as bright as day; and well may we ask from what source they did draw all that beeswax. I believe it was produced in great quantities by clergymen themselves, as the instance of St. Samson mentioned above testifies. This

was so well known that the ancient laws of Spain made the provision that clergymen might pay their taxes in wax instead of money if they chose to do so.

An instance somewhat similar is connected with this abbey. By a charter (of which the original is still extant) given to the monks of Buckfast in the year 1216 we learn that the (then) abbot agreed to give on the patron feast of our abbey one pound of beeswax to all our knightly benefactors in order to keep alive the memory of their gifts. The distinguished company, before signing that charter in our chapter room, had, no doubt, visited our garden and had seen a good range of bee-hives as now, and nothing, therefore, more natural than that they should suggest an annual pound of beeswax as a recognition for their liberalities. We are not left to ignore, however, that a lady disagreed to this, and, when the document was brought to her to be signed in the guest-house (for, according to monastic customs, ladies are not admitted within the enclosure), she asked to have a pair of white gloves instead of the beeswax, which request was easily granted, as Buckfast Abbey was then the great center of woollen manufactures in Devonshire. Perhaps the reason that beeswax can now be gotten so easily causes us to cultivate bees on less extensive lines. But still, even now I know of more than one Lord Abbot who does not think it below his dignity to look after these interesting little creatures, and within the last two years it has been my own privilege to help in introducing bees into two newly established monasteries.

The following is a curious example of what may be done with bees. I know of a clergyman who set twelve stocks of bees on a piece of land granted to him on lease. They prospered so well that in a remarkably short time he not only paid for the land, but also built on it a nice parochial church almost entirely with profits derived from his bees. This has set me thinking how much I wish we could do the same here, for we have just started rebuilding our old monastic church to the memory of the late Lord Abbot who perished last August in the wreck of an Italian steamer while on his way to visit our American brethren. He loved the bees so much that, on his tour to the United States two years ago, he brought us some seeds of your bee flora. This will explain why the present writer is anxious, that, in their turn, these sweet pets should contribute in some way their little quota to the erection of the monument in memory of the popular and beloved deceased. But sharing not in their capabilities the same confidence as the above-mentioned clergyman, he has deemed it more prudent to exchange temporarily the fragrant air of the apiary for the dusty studio, as illustrated in the enclosed photo.

Our apiary is beautifully situated in a valley, and a more ideal place could scarcely be found for bees. It is protected on all sides against the wind, and is, during spring and summer, like one of nature's Edens. One side of its secluded precincts is wooded with the fragrant thuja; on the west and north is a long low wall of which the stones are intermixed with *Arabis Alpina* and *Aubrietas*, which, forming a solid mass from end to end, descend to the ground like a graceful carpet, while their snow-white cross-shaped flowers

spread their chaste perfume all about. Behind and above that wall, as if to shelter the sweet fragrance from the north wind, rise the golden broom and roses with their delicate colors, while gorgeous hues of wild flowers and ferns fringe with beauty the banks and braes and streams around. Two rivulets of clear water crooning under the ferns and trickling down from stone to stone, in their gentle embrace enclose the apiary, mingling their tiny voice with the aerial hum of the busy throng, whilst hard by in the dim shadow of its woody bank a mighty river, the Dart (called for its picturesqueness the English Rhine) winds along its poetic course. A few yards further lies a placid sheet of water, beautiful beyond expression, in which monstrous salmon weighing from 15 to 20 lbs. show us their glittering silvery scales. On the northwest of the apiary, a mile away, appears the imposing cone-shaped Hem-bury Hill, once a Roman camp, and historically connected with St. Mary's Abbey at the time when the heroic Britons made of it their stronghold against their Saxon invaders. From its summit may be viewed a panorama of matchless beauty, especially toward the venerable abbey among whose possessions it was reckoned centuries ago. Every year in late summer our bees animate its crimson-colored crest with their thousand thanksgiving hums.

The valley of the Dart is one of the loveliest parts of lovely Devonshire, and its nameless charm casts its spell even on Americans, of whom several come every year to spend their holidays under the shadow of the old abbey.

Buckfast, England.

## THE TROUBLES OF AN AMATEUR BEE-KEEPER.

### A Fools-day Experience.

BY F. DUNDAS TODD.

[It will be remembered that Mr. Todd is the gentleman we introduced in our issue for April 15, page 496. He has written a series of articles telling the experience of an amateur. The story he tells is very interesting, and will bring many a smile from those who have "been there" too. While it is the experience of an amateur, we feel sure that even the veterans, if they will read down the first paragraph or two, will be compelled to read the whole story.—ED.]

Trouble and bee-keeping are, in my experience, synonymous terms. I bumped into trouble the very instant I bought my first hive, and have been in it more or less ever since. Any man who can not enjoy troubles, who is not happiest when he lives and sleeps with them—aye, dreams of them—has no business to be a bee-keeper. I never yet cared for a pastime that anybody could make a big success of without mental effort; and possibly it was because bee-keeping looked so simple that I passed it by when choosing a new hobby. In a way bee-keeping was thrust upon me, and it has filled up at least four hours of my day or evening ever since I got the shock.

My family have been for years big honey-eaters, consuming at least two 60-pound cans every winter, and often I would threaten to keep a bee and raise my own honey. Then I got acquainted with a bee-journal editor and subscribed to his journal just to get a general idea of what bee-keeping looked like. Then, following one of

my rules, I bought a book on the subject, read it, and placed it in my book-case. Bee-keeping looked easy, and I had no desire to waste time on it.

Then the blow fell. A neighbor moved his home a thousand miles, and left his bee-hive behind him—one bought the summer before. Nobody in the village would touch the varmints at any price, and at last they were unloaded on me as being the easy mark that tackled almost any thing. Surely I was not afraid of bees? Of course, I was not. Then they ran themselves, required no care of any kind—all I had to do was to take the honey at regular intervals. The best thing to do with temptation, I have found, is to give in at once and get the matter off your mind; so I succumbed, paid the small price asked for the complete outfit, and shortly discovered that I had found a big exception to my rule. The little demons got on my mind in short order, and have been there ever since.

It was April 1 when I bought the hive. I inspected it in the yard where it had spent the winter, with practically no protection from the cold blasts that circle round Lake Michigan. A few bees were flying merrily, so I decided that night would be the best time to bring them home, since at that time all of them would be nicely tucked in their little bed and I would have no trouble—none at all. Just to make sure of them I would nail a strip of wood over the entrance, but the precaution was probably needless.

At 8 P.M. that night I set out with a wheelbarrow and a lamp for my hive. I nailed on the strip in front, and was amazed to hear an awful rum-pus at the first stroke of the hammer. But I had the wild beasts safely caged, so it was all right. Carefully I swung the hive on the barrow, without mishap. For a mercy the bottom-board held, but no credit is due me, as I thought all bottom-boards were an integral part of the combination. It is not what we know that bothers us, but what we don't know. Five minutes later my ignorance brought the inevitable result; the punishment more than fitted the crime; in fact, it had enough surplus material left over to make several extra habits, including one of strong language.

In my own yard I had placed four bricks in the very worst location I could have selected—one that was open to all the cold northwest blasts for which Chicago is famous. As I was placing the hive in position, aided a little by the feeble light of a stable-lamp, carried without discretion by my boy, I heard the bottom-board drop, and then it seemed as if ten thousand needles had been suddenly thrust into the points of my fingers. A quick glance showed me an army of black smudges rushing all over the sides of the hive, so it was dropped into position and I beat a hasty retreat. It was the worst April-fool stunt that ever had come my way; but I draw a veil over the rest of that evening's doings and sayings, especially the latter.

What had I done wrong? Now I turned to my own book and the ones that came with the outfit; but, oh what an awful tangle every thing seemed to be in! even the catalog was confusion tenfold—so many different kinds of hives; but mine was unlabeled. Bit by bit I learned that bottom-boards and hive-covers are unattached

but essential parts of any well-constructed hive, and that in the case of moving they ought to be fastened thereto. As my fingers and ankles ceased throbbing I felt less vindictive toward the manufacturer, but more determined to know more about hive construction.

Day after day I studied the catalog, and carefully read through the caption "Hives" in the A B C book, and often with the catalog in hand I would put this question to the Sphinx: "What are you, anyhow—a Hoffman, a Langstroth, a story-and-a-half, or a Danzenbaker?" and, sphinxlike, it answered nothing.

What I did not know was bothering me a whole lot. At last I got some relief. One night I was called to the telephone. "Say, Todd, is it true you have a hive of bees, and that the little wretches have about laid you out?"

"Yes, and no; but where do you come in?"

"Oh! I kept bees when a boy, and I am just dying to get my hands on a hive. I know all about skeps, but have had no experience with frames."

Result, we combined our forces and investigated the inside arrangements one afternoon in the midst of a cold northwest wind. My friend thought he saw the queen, a miserable little runt he called it, but there were a few drones out and lots of drone-cells. I took his word for it in every thing. We assumed the hive was a Danzenbaker, after a study of the catalog; but I refrain from saying how often I measured the outside dimensions of that hive. My mind now got some repose, and I thought my bee troubles were all over, and so turned my attention to my cold-frames. Soon, however, I noticed each evening an awfully big heap of dead bees in front of the hive. I would lay a piece of paper on the ground, and the next night I would find a hundred or two of dead bees on it. Then drones were flying freely, and I began to suspect that something was wrong.

Back to the books again. Gentle reader, did you ever hear of "Buchan's Domestic Medicine"? It was a household work in Scotland fifty years ago, and many nervous people put in nearly every spare minute studying the symptoms of every disease so as to locate their own. One man I knew was said to be convinced that he had most of the symptoms of every disease mentioned in Buchan, including those of a condition that can not possibly occur to a member of the male sex, and I often thought of him as I burned the midnight electric light over such parts of the A B C as are devoted to diseases. Not finding the exact symptoms I proceeded to read the whole book, and at last struck "Bee Paralysis." This was the nearest I could get; but it did not properly cover the ground. One thing I was sure of—lots of my bees did stagger around on the alighting-board as if drunk or paralyzed, and were hustled off by their cruel-hearted sisters. They were black and greasy in appearance, as described in the book, but their abdomens were not swollen. And the drones got more numerous, making the welkin cheerful with their hum. Another examination of the inside of the hive showed fewer bees and more drone-cells. Verdict, hive no good; cause unknown.

Medford, Oregon.

*To be continued.*

## CAUCASIANS THAT EXCELLED ITALIANS.

**They Capped the Honey Whiter, Entered the Supers more Readily, and were Easily Distinguished from Blacks.**

BY C. W. PRICE.

[The following article by Mr. Price, in praise of the Caucasians, may draw out some protests from some of our subscribers who have tried these bees, and who report they are no gentler and no better in any respect than Italians. After some of these protests had come in we held back one article praising these bees, and the writer of it felt that we were not fair in that we allowed an article to go in condemning the bees, and yet refused to publish his in praise of them, as he had found them to be eminently satisfactory. We are now publishing both articles, and will endeavor to publish any unfavorable ones as well as any that may come in praise of them.—ED.]

I notice that the different writers are divided as to the value and importance of Caucasian bees. This being the case, I think they should be thoroughly discussed, and all of the good or bad points fully brought out.

When these bees were first brought to my attention I was at once seized with a desire to try them. Situated as I am in town with neighbors on each side, and with only a small tract of ground, I thought that, if I could get a strain combining prolificness with gentleness and good honey-gathering qualities, I could well afford to make a change. I had commenced with black bees, then I changed to Italians with some hybrids mixed in with them. I like the blacks fully as well as the Italians. They stored more honey for me, and capped it nicer than the Italians, and would enter the supers when Italians would not. The last year I had the Italians the two strongest colonies refused to go into the supers, and, try as I would, they would not and could not be induced to go above. They would cram the brood-frames with honey, and then swarm. The hybrids did better for me than the Italians. They entered the supers as readily as the blacks, and capped the honey nice and white. Then the Italians are apt to change their minds about being gentle, and surprise you when you are unprepared. I found that they could be cross on short notice.

Early in the season of 1906 I procured several tested Caucasian queens from different places. Two of these queens were select breeding queens, and all of them were fine ones. During that season I raised and introduced Caucasian queens into all my hives. In the fall of that year I received an imported Caucasian queen from the Department of Agriculture at Washington, introduced her, and she proved to be a good queen.

The year 1907 is generally considered to have been a very poor one for the production of honey. This is the report brought to me from over this county, and all bee-keepers whom I have seen report the season as a poor one. Regardless of this fact, and the still further fact that I had but little time in which to look after my bees, the Caucasians gave me more honey than was obtained by my neighbors or by any one in the county so far as I am able to learn. I had more honey per colony than any one near me, and there are a number of bee-keepers here. My Caucasians beat them all. They built up very rapidly in the early summer—so fast, in fact, that I was surprised to find them so strong with bees

when the honey season opened. They swarmed about as much as the Italians had been doing, but were more gentle when being handled. When it came time to put on the comb-honey supers they were all in good condition, and I was pleased with the way they entered the supers and commenced work. If they continue to be as good honey-gatherers as they have been so far, no more of the yellow beauties for me. They capped the honey nice and white, and the work in the supers could not be surpassed by any bee. No discount on them there. The two first supers to be removed, which were a fair sample of all I obtained, were so nice that I took the 64 sections out of the supers, and had the honey photographed. I inclose a picture of the honey as it appeared then. This was not sorted over, nor any particular super selected for the purpose. It was just a fair sample of what I obtained.

There seems to be something about them that makes them all want to defend their hive when attacked. When the weather is not favorable for handling bees you will find the Caucasians about as cross as any bee you may meet. They will fight like tigers if you attempt to handle them when the weather is cool. Leave them alone then. They are good defenders of their homes, and are seldom robbed by other bees. In handling them they will remain on the combs just like Italians, and are in some ways very much like them.

The color is enough different from the blacks so that they may be readily distinguished from them. They raise lots of drones; and, consequently, if you were to have Caucasians introduced into your yard the chances are that, with the large number of drones raised, they would be likely to remain pure Caucasians. They will

FIRST TWO SUPERS TAKEN FROM A COLONY OF CAUCASIANS IN 1907.

This shows the average quality of the sections, as no effort was made to pick out good supers.

I have found the Caucasians more gentle than the Italians, and with me they have stored more honey, capped it nicer, finished off the sections just as nice, put less propolis on the sections, and did not attach so many of the sections to the separators. This last was quite an objection to the Italians, for in some seasons they would attach so many sections to the fence separators that it was quite a loss, as more or less of them would be damaged in being removed from the supers. Now, there is quite a difference in bees in more ways than one. I have found that, while the Caucasians are gentle and easily handled when the weather is warm and they are at work, they must be left alone when it is cool and cloudy.

start a large number of queen-cells, and are good bees to have if you wish to raise queens, as they will care for more cells than Italians or blacks.

The one principal objection to them seems to be their habit of gathering propolis; but I think this is being greatly exaggerated. I find less propolis on the brood-frames and on sections than before I had them. It is a fact that they will gather a large amount of propolis and deposit it at the entrance to the hive in lumps as big as the end of my thumb; but this is about as good a place to have it put as I know of; in fact, this is where I want to have it left, then I can raise the hive off the bottom-board, scrape it off, and it is done with.

My advice to those who have the Caucasians is, do not be in too big a hurry to condemn them. They have proven to be all right with me, and they will do so with you if given a chance. Too many condemn them without giving them a fair trial. There are bees and bees; but you can not find the bee that will please everybody: it is impossible. If you are so situated that your bees can bother no one, then the gentleness of the Caucasians will not appeal to you so much. Those who are living in town, and are timid about handling bees will find the Caucasians very satisfactory.

Spirit Lake, Iowa.

[Our correspondent believes that the Caucasians are enough different in their markings to be readily distinguished from black bees. Some may differ with him in this. It will be remembered that one of our correspondents, some time ago, sent by mail some cages containing samples of Caucasians, blacks, and Carniolans to some of the expert queen-breeders. They were unable, by the markings of the bees, to name them. There *is* a difference, but it is so slight that the great majority would not be able to distinguish one type from the other. In point of behavior there is a marked difference between blacks and Caucasians. The difference in markings between Carniolans and Caucasians is more distinct than between Caucasian and black bees. The Carniolans are slightly larger than either, with a bluish-black cast, while the Caucasian and German bees are of a grayish black; but the Caucasians are a little brighter, the fuzz-rings showing more distinctly.—ED.]

A WHOLE APIARY TO BE CAUCASIANIZED; ONE-THIRD MORE HONEY FROM CAUCASIANS THAN ITALIANS.

On page 42 Mr. F. R. C. Campbell writes that he has two Caucasian colonies from Washington that did not gather as much honey as Italians and hybrids, but that they plastered fences and sections with propolis.

I wish to report that we have 35 colonics, also from Washington, D. C., that put up 160 lbs. of fine section honey per colony the past season, besides filling 75 lbs. in the brood-chamber at the close of the season, which was one-third more in every case than the best Italians did. Eighty stocks of Italians are in the same yard with them.

OUTDOOR COLONY FOUND ON SUGARLOAF MOUNTAIN, NEAR BOULDER, COLORADO.

Our Caucasians filled the entrances with propolis at the close of the honey-flow, but carried none into supers. The sections and fences came off as white and clean as when put on, needing no scraping.

Veil and smoker were a necessity with Italians all the season, and stings were frequent and severe. With Caucasians no veil, smoker, or hat was used, and no stings received; so we have concluded to Caucasianize all our apiary.

E. A. MORGAN.

Vermillion, S. D., Jan. 11.

## A LARGE OUTDOOR COLONY.

BY C. H. HOWARD.

In a store here are several combs built on a bough of a tree. It is the largest outdoor work of bees that I ever saw, for it would accommodate quite a large colony. The store-keeper let me have them to get a photograph made, as shown herewith. He informed me that it was found last year on Sugarloaf Mountain, which is about 17 miles from here.

Boulder, Col., Feb. 14, 1908.

## QUEEN-REARING FOR WOMEN.

### Many Queens Lost at the Second Introduction in Baby Nuclei.

BY MRS. J. W. BACON.

I have been rearing queens for the last ten years, at first for my own use and then selling a few. About three years ago I sent for the book "Modern Queen-rearing," and a queen-rearing outfit, and have raised and sold some very nice queens. The small nuclei boxes that are seen on the fences are home-made, each holding two Danzenbaker sections fastened to the cover. We always have some partly filled sections that we can use in this way. This saves the time, trouble, and expense of having the small frames filled by the bees. It does not pay to try to start these small boxes too early or before there is a honey-flow; and a good teacupful of bees should be used in each one. I have some of these boxes hung in a hedge. Of the first lot of queens introduced I lose very few. It is not so easy to introduce the second queen.

The plan of caging a virgin queen for a few days in the nucleus before taking the laying queen away is but a beautiful romance. How I do wish it would work! but I find her dead nine times out of ten. I have the best luck with the ripe cells put in a few hours after taking the laying queen away; but I use what I have at the time. If I have virgin queens in the nursery cages I put them in just at night of the day I take the queen away.

However, I introduce the second queen to these little boxes; and when I take these out I let these boxes go for the season, as they will all be robbed out as soon as the honey-flow ceases. I have always lost about half of this second lot. They may be too near the old hives; but it is a

very handy place to have them. We have a number of dovetailed hive-bodies with a division-board in the center, and an opening at the back of one side. This makes two three-frame nuclei. I hardly ever lose a queen from these. They are the best for early and late queens.

I hear some one ask if it pays. If you count the satisfaction of being master of the situation, the benefit of outdoor exercise, and if you love to work with your bees, it pays well; but if you are looking only for the dollars and cents you had better let some one else raise the queens, and run your bees for honey.

Waterloo, N. Y.

## EXTRACTED-HONEY PRODUCTION.

### Getting the Honey off the Hives; the Locality and Method Whereby Large Quantities of a Superior Article May be Secured in a Leisurely Fashion at a Low Cost.

BY W. Z. HUTCHINSON.

*Continued from last issue.*

I have already mentioned the use of escapes in the removal of the honey; but when ten-frame Langstroth hives are piled up four and five high, the putting-in of the escape-boards is no light task, especially for one man; and I have tried to plan all of my work so that one man can go to an outyard, all alone, go on a wheel or in a trolley car, or in some such manner, and go on and do the work to advantage without any assistance. I would have a honey-house and full complement of tools and appliances at each yard; then, during the working season, all that has to be carried from one yard to another is simply the man himself. But, to return to the insertion of the es-

MRS. J. W. BACON'S QUEEN-REARING YARD, WATERLOO, N. Y.

cape-boards. Of course, one end of a super can be raised up slightly, the board shoved in as far as possible, then the super lowered and the board and super shoved along until both are in their proper places; but this is difficult and unpleasant both for the operator and for the bees. A hive-lifter could be used for this purpose, but I have an arrangement that is more easily and quickly put in place and used than would be the case with a hive-lifter. This is simply an iron lever a foot and a half long, with one end widened out or split into two sharp prongs that can be thrust into the hand-hole of the upper hive; then, back about four inches from the pronged end, is an iron support hinged to the lever, and the lower end of this support is also split into two prongs that can be thrust into the hand-hole of the lower hive. When the end of the lever is depressed, the upper hive is raised. The depression is continued until the lever and its support are parallel, when a wooden pin is thrust through two holes that come opposite each other; thus the levers are held in position, the upper hive being elevated about an inch and a half above the lower hive. That is, the hive is raised that much upon *one* side, when I go around to the other side and put in a lifter on *that* side, when the upper hive is held an inch and a half above the lower one, and it is an easy matter to slip in an escape-board and then lower the upper hive into place. In order that the wooden pin may not be dropped or lost it is tied to the end of a string fastened to one of the levers. It is also possible to use these levers when putting queen-excluders in place.

From the description of the levers and their manipulation, it may seem like a rather slow and tedious operation to put them into use; but actual practice shows it to be the opposite. If the weather is warm and the propolis soft, the levers alone can be depended upon to loosen the hive; but if the weather is cool, the hive had better be loosened first with a screwdriver. First, raise the hive a little bit—not quite enough to let out the bees; then drive smoke into this crack, and the bees will be out of the way when the hive is raised.

After the escape-boards are in place I go over every hive carefully, *CAREFULLY*, to see that there are no cracks that will let bees into the super after the inmates have gone down through the escape. One who has never used escapes will be surprised how small a crack will let in a bee. The best of any thing that I have ever found to stop up these cracks is soft clay. Find some stiff clay, just about such as would be used for making bricks; moisten it, stir it, and work it until it is of just about the consistency of putty. Take a ball of this in the hands and go around and examine all the hives, plastering some of the clay putty into every crack. I never knew the bees to try to dig out the mud, and it soon hardens down as hard as a marble.

At each one of our apiaries we have a place to sleep and cook, even if it is only a tent, and we can go the day before we are to begin extracting, and put a bee-escape under the top super of every hive. The next morning most of the supers will be free from bees, and we can begin taking them

LEVERS FOR LIFTING HIVES WHEN PUTTING BEE-ESCAPES IN PLACE.

The hive at the left shows the lever in place. The one at the right shows the handle of the lever depressed and the pin in place.

off and putting the escapes in under the next story. As we begin taking off the honey we also begin warming it up, and, when warm enough, we begin extracting. You will notice that there are really four operations: Putting the escapes in place; wheeling the honey into the honey-house; warming up the honey and then extracting it; and, once the work is begun, it is easy to follow out a sort of routine in the work.

I wonder if I might be pardoned a few words of comparison with the ordinary method of extracting. The hardest and most disagreeable part of the work is that of getting the bees off the combs. At best it is unpleasant for both the bees and the operator. The weather is almost always hot; and the smoking and brushing, especially the latter, make the bees cross; and between the heat and the stings and the mussy character of the work the poor bee-keeper has any thing but a good time. It is not so bad when honey is coming in; but there is always some of this work to be done at the close of the season, when there is robbing to contend with. The use of the bee-escape cuts out all of these unpleasant features. Instead of several men working all day in a sort of mild torment (and sometimes it

isn't so very mild) to get the bees off 5000 pounds of honey, one man can put on the bee-escapes in half a day, and really enjoy the work if he uses some lifting-arrangement such as I have described. Don't you see how these two things, plenty of empty combs and the use of bee-escapes, can change the whole aspect of extracted-honey production? They do away entirely with the hurly-burly of hurried extracting in hot weather. Not only this, but this plan allows one man to care for several apiaries all alone. It is a very short job to put on empty supers or supers of empty combs; and it is not necessary to wait until the very minute they are needed before putting them on the hives. By careful watching, and keeping slightly in advance of the work, it is an easy matter always to have abundant room on the hives, even though there are several apiaries to care for. Then when it comes time for extracting there is no special hurry about it; the work at one apiary can be finished up, then taken up at another, and so on, going from one yard to another until the work is all done, no matter if a month or six weeks are consumed in the work.

#### WARMING UP THE HONEY.

The first year we warmed up the honey with a

base-burner hard-coal stove. This gives a very even, steady, desirable heat; but it is too expensive, and not very practical, to have a hard-coal stove at each apiary in the woods of Northern Michigan; so, last year, we used a Perfection oil-heater, costing about \$5.00, capable of burning a gallon of oil in about eight hours, although much less can be burned. This is the first oil-burning stove, using a wick, that I ever saw that could not be made to smoke. It has a cylindrical wick, and just above the wick is a round plate of iron called the "flame-spreader," and the wick is turned up until it strikes this spreader, when it can go no higher, and it won't smoke, and can't be made to do so.

One end of the honey-house or cellar is partitioned off, making an "oven," as we call it, large enough to hold 50 or 60 supers. We fill this up at night, for instance; light the stove before we go to bed, turning the wick up part way so that the temperature in the upper part of the room will stand at about 100 degrees. In the morning we refill the stove, turn it on full blast, and go to extracting, taking the first supers from the top of the room. As some of the piles are lowered, more supers are taken from other piles and added to these, thus bringing more honey up into the heated "zone." As fast as there is vacant room, more supers are brought in; and a sort of routine is followed whereby one always has hot honey to work on while more is heating.

So far as results are concerned, this plan of heating is satisfactory, but there is one decided objection; and that is, the handling of heavy supers of honey in a hot room; and we have in view the adoption, this season, of a different plan that was suggested by Mr. Elias E. Coveyou, of Petoskey, Michigan. Part of the room will *not* be partitioned off, as before; but, instead, a box, or sort of "well," will be made below the floor, at one end of the honey-house or cellar, in which to set the

stove. Across the honey-house, upon the floor, just above the "well" containing the stove, will be built a box, several inches deep, as wide as the length of a hive, and extending clear across the room. Side by side, along the upper surface of this box, are to be openings nearly as large as the bottom of a hive or super. When the fire is lighted in the stove the heat will rise up into this long box and pass along its entire length; and if the openings were left uncovered it would pass out of them into the room; but over each opening is to be stacked up a pile of supers of honey, perhaps four or five supers high, with a cover on the top of each pile. The heat will rise into these piles of supers, and be retained there, warming up the honey—the upper super becoming the warmest first. As the upper super is taken off to extract, the cover will be placed on top of the next lower, which thus becomes the topmost super, and will receive the greatest amount of heat. In this way there will be no lifting and piling about of supers. Once they are stacked up over these openings, they will not be moved till taken away to be extracted, the top one always being the hottest, even though it may be the only one left over the opening. When heating honey in

G. F. JONES' APIARY IN NORTH CAROLINA.

The hives are set up on high foundations to prevent the toads from eating the bees at night.

a room, the great difficulty is that the heat rises to the top of the room, perhaps also melting the combs in the upper tier of supers, while those next to the floor are quite cool—too much so to extract—and there is no way of heating them except to raise them to the top of the room. It is evident that Mr. Coveyou has solved the problem of heating the honey without heating a room, and without piling the supers over after they are once in place.

*To be continued.*

## BEE-KEEPING IN NORTH CAROLINA

### Why Bees Rob During a Honey-Flow.

BY G. F. JONES.

We had a fine honey-flow here last season. Our principal flow is sourwood, which gives a very fine-flavored honey, water-white. The flow lasted 27 days. We have two robbing seasons—one in the early spring and one in the fall. On the 23d of September last we had a fine honey-flow, but my bees were robbing the worst I had ever seen them. I should like some of your experienced bee-men to tell me why the bees rob during a fine flow. Our fall flow is from the frostweed, which is the last to bloom here.

I am sending you a view of the home of my bees. I have 16 colonies, which gave me an average of 70 lbs. One of my colonies gave me 140 lbs., which I sold at 17 cts., or \$23.80, from one queen. I have my hives on foundations 8 in. high, and just the width of the hive, and sloping, as you will see in the picture. I arrange them this way so the toads and frogs, which are very numerous here, can't pick up my bees at night. I notice them trying to catch the bees at night;

but when they make a dive they turn a somersault every time.

I have been keeping bees for three years. I started with one colony, and have built up to 16. I have had several reverses and many gloomy days with my bees, but I just consult my old standby, GLEANINGS, and it always pulls me through.

Elkin, N. C., Oct. 9.

[You say you were having a "fine honey-flow." We can hardly believe this was possible. It would be our opinion that there was some honey coming in, but not enough to keep all the bees busy. Sometimes during a light honey-flow some colonies will be busy while others will be robbing; but during a honey-flow, if at all strong, all bees will be engaged in gathering honey.—ED.]

## MICE IN CHAFF CUSHIONS.

### Colonies Prepared by Placing Large Boxes over Paper-wrapped Hives.

BY SARAH B. LEEDS.

These pictures are of bees kept by two young women in Pennsylvania. In order to shelter the colonies for the winter, last year we put a super on each hive with a bag of chaff inside, then tacked builder's paper around the hive, and over all placed a large packing-box—Fig. 1.

The bees were in good condition in the spring, but we found the field-mice had made nests for themselves on top of the hives, and had gnawed off a good deal of the paper under the box, as shown in Fig. 2. Several weeks later we looked into the hives to see how the bees were getting along, and found a large nest inside of one of the

hives, with the mother-mouse and several little ones, the combs having been badly eaten to make room for the nest—Fig. 3. Perhaps this might not have happened in a stronger colony, but the queen had died and the bees dwindled and seemed discouraged.

West Chester, Pa.

## PREVENTION BETTER THAN CURE.

### Painting Cracks and Entrances to Prevent Robbing.

BY R. M. SPENCER.

I notice an article in the Sept. 1st issue, page 1131, in regard to the robber-trap invented by J. F. McIntyre, who resides only fifteen miles from me. Being a good friend of Mr. McIntyre, and claiming his way of stopping robbers by use of the trap is good, I wish to write only on the subject of the prevention of robbing, which will do away with the use of any trap.

A few years ago I saw a short article in one of the journals in regard to the use of fresh paint as a preventive of robbing. The idea looking good to me I tried it; and to say it was a success is putting it mildly. The directions were to use paint the same color as the hive, but I add a small amount of turpentine. In beginning to open colonies of bees when they are inclined to rob they will show signs of robbing after you have opened a few; and as soon as these signs show I get my paint and brush, and paint all cracks under the cover and between the super and brood-body on all colonies that I have looked into. To see these bees pounce on the cracks of hives they have started on is amusing, because, as soon as they do so, they alight on this fresh paint and get off from it at once; hence they will

FIG. 2.—OUTSIDE BOX REMOVED TO SHOW THE PAPER. WHEN THE HIVES WERE EXAMINED IN THE SPRING, MOUSE-NESTS WERE FOUND.

not hang on any hive in clusters or in long strings as they do when they begin the robbing. This, then, confines the robbers to the hive that you are working with; but as soon as you close

it, and paint all cracks, they will bother it no more, and you can look over a yard of bees by using this method, and have little trouble, and also be painting part of your hives. But if robbing is so bad that the bees begin to get in the entrances I do not close them, but paint all the alighting-boards and about two inches above on the hive-body, as the robbers always alight either on the alighting-board several inches back and crawl

FIG. 1.—COLONIES PREPARED FOR WINTER.

A super containing a chaff cushion was placed over each hive, and building-paper wrapped around it. Finally a large box was placed over all.

FIG. 3.—COMBS EATEN BY MICE IN THE SPRING.  
*See preceding page.*

into the hive, doing the same above on the hive-body. But any of the bees of the hive being robbed, in returning make a straight dive and go into the entrance clear of the paint, and in a short time every thing will be quiet. I know I have saved a great many colonies by this method on my territory; and I think it will work elsewhere as well.

Nordhoff, Cal.

[Prof. H. A. Surface, zoologist, in the employ of the Agricultural Department of Pennsylvania, conducted some experiments in the use of paint to discourage robbers that were hanging around the hives, and his experience was about the same as yours. We may say that plain turpentine will answer almost as well; and a solution of carbolic acid and water painted on would also be nearly as effective. There would be one objection to the use of paint; and that is, that the cracks of the hive might get too many coats, giving it a rather bad appearance.]

It may be said that robbers should not be allowed to pry around the cracks of a hive; or, rather, we should say they should not be permitted to get into this bad habit. Where robbing is rampant, hives should be opened only while it is rainy or growing dark; or, better still, the operator should get inside of a cage to handle the hive during the day. If hive after hive is opened during the robbing season, and two or three hundred bees are allowed to pounce down on the combs while the colony is opened up, conditions will get so bad as to make work intolerable, with the result that there will be hundreds if not thou-

## FOR WHICH WILL YOU VOTE ON ELECTION DAY?

VOTE AS YOU WOULD HAVE YOUR  
BOY BECOME.

You may vote to license saloons to make a drunkard of *my* boy, but I will never vote to license saloons to make a drunkard of *your* boy.

THE MILLS THAT GRIND.

The ginmill can no more run without boys than a sawmill can run without logs or a flouring-mill without grain. The only question is, whose boy shall it be, your boy or mine, our boy or our neighbor's.—*See Temperance Column.*

sands of robbers that will be continually prying around the cracks of the hives and the entrances of weak colonies. There is no advantage in working in this way. The hives should be opened early in the morning or late at night, or by moonlight. One can do very fair work providing an attendant holds a lantern. In a word we may say, be careful to avoid the robbing habit; for when it is once started in a yard it is likely to continue throughout the season, causing no end of annoyance and loss of bees, and a continuous uproar in the yard.—Ed.]

## IS THERE A PERFECT LOCATION?

### Some Observations from a Bee-keeper Who has Traveled all Over the United States and Cuba.

BY LESLIE BURR.

I have been in almost every section of the United States that has the reputation of being a good honey-producing country, and I spent the greater portion of four years in Cuba. While there I visited all of the provinces and worked bees in half of them. What I intend to do now is to show what the conditions are in various parts of the country.

First we will go to California and take a look at conditions there. The bee industry is of such importance that you can hear the prospects of a honey crop the coming season discussed at the hotels in the cities, or at the corner groceries in the small towns.

And then when you see the sage-covered hills, with not a foot of them under cultivation, you say, this is surely a bee-keeper's paradise, and so it would be if the sage yielded every year. But it does not, and the bee-keepers often think they could improve their condition by making a move, and wish that they were in Arizona or some other place where fog is unknown.

In Arizona and New Mexico conditions are much the same, for you are not always sure of a honey crop. Since there is no rain, the bee-keeper has to go where there is irrigation, and he has but one thing to depend upon for his surplus honey, alfalfa. And if you think that an alfalfa region is a bee-keeper's paradise, divest yourself of the thought; for, while there are several crops of hay cut each season, the period of bloom is so short that it takes several months to get as much honey as would be obtained in the same number of weeks in the North.

Then there is that great State, Texas, where you can get any thing you want in the line of climate, where you can travel in a direct line as far as from Chicago to New Orleans, and still be inside of the State lines, where you can spend the winter at Corpus Christi out of doors and then go into the pan-handle region in May and find a blizzard raging.

But, to come back to the question of bee locations. Texas has her share; but do not expect to find them everywhere. There are parts of Texas as large as the average Eastern States where it would be impossible for bees to live, let alone gathering any surplus. And Texas is the same as the previously mentioned localities.

You are not certain of getting a crop. The mesquite is a freak, like the sage of California or the black mangrove of Florida, in that it yields only when conditions are right.

Possibly, now, your thoughts have strayed to Colorado, and in your mind you have pictured the great alfalfa-fields, with the mass of sweet clover growing along the irrigation-ditches and road-sides. What you will generally find is that a great portion of the alfalfa is cut before coming into bloom. But you argue that it has been proved that it is a loss to cut alfalfa at such early periods, and it is only a question of a short time until the farmers will let it bloom as in years gone by. But such reasoning is mostly "hot air," for, as a rule, where the early cutting of alfalfa is practiced the hay is used for feeding sheep, and alfalfa for sheep has to be cut before coming into bloom.

Then there is such a thing, in parts of Colorado, as overstocking. I know of one crossroads where there are three apiaries almost within a stone's throw of each other. Each of these apiaries belongs to a well-known bee-keeper. There is another section of the State where there are ten thousand colonies within a space of twenty miles square, and the size of the apiaries is such that a Californian or a Cuban would hardly feel justified in calling them an apiary.

So much for various parts of the country. But do not think that I mean it is impossible for one, no matter where he is, to be able to benefit himself by a change of location. Not a bit of it. I believe that, to make a success of bee-keeping, one must have a good location, and that the man and hives are secondary. But what I do want to say is, that nowhere is there a great bee paradise which one can find by moving one or two thousand miles; and that he who wishes to better himself can most likely do so just as well by moving fifty or sixty miles as a thousand; for, from my own observations, there are still a number of good locations in the North that are not overstocked. The old Spanish explorers sought for their visionary Eldorado, but it was never found; and so it is with the bee-keeper who thinks that somewhere there is a perfect bee country. It does not exist.

Valparaiso, Ind.

## PERFECTION IN BROOD - COMBS WITHOUT WIRE OR SPLINTS.

BY WALTER S. POWDER.

Having received many inquiries about wiring, and using splints in brood-frames, and as many of these inquiries are from readers of GLEANINGS, I should like to explain the method which I have found most satisfactory. In short, I use neither wire nor splints; but having my combs perfect is one of the hundred things that I am "cranky" about. I have had considerable experience in extracting and in shipping bees, and once thought that wiring was absolutely necessary; but with horizontal wiring I found bulged combs, and in vertical wiring the wires along the top-bar were very unsightly to me, and the bees seemed to want to store propolis along these wires, and to me the work of wiring always seemed very tedi-

ous. I use full sheets of medium brood foundation, but I cut it down so that it does not reach the end-bars by half an inch, or the bottom-bar by  $\frac{3}{4}$  inch. The whole secret seems to be in giving these full sheets to the bees, and I do this by inserting one frame at a time in the center of my hives, allowing the bees to have an equal force on both sides of the foundation at the same time. If foundation should touch the end-bars the bees would proceed to fasten it before it could hang plumb.

Some one may ask, "How about extracting from such combs?" I would not extract from them at all, but would work new combs into the brood-chamber and always extract from combs that had been used for brood at least one season. In shipping nuclei I select such combs as have seen at least one year's service, and I have never had reported a single instance of a comb breaking down.

I have also considered it desirable to have my combs built to the bottom-bars. To accomplish this I cut a good comb lengthwise into strips about  $\frac{7}{8}$  inch wide, using a sharp thin-bladed knife. I then lay a comb on its side and trim off about  $\frac{1}{4}$  inch from the bottom, and then insert one of the strips and place it in the second story of the hive during a honey-flow, and within 24 hours the work is completed. On this plan I have a stock of combs that are more beautiful than any wired combs I have ever seen.

Indianapolis, Ind., April 25, 1908.

## THE IMPORTANCE OF HAVING QUEEN-CELLS FINISHED BY STRONG COLONIES.

BY JOHN M. DAVIS.

I do not wish to pose as a critic; but I beg to call attention to Mr. Wm. W. Case's method of keeping "the apiary supplied with a class of queens having no superior on earth," page 363. His selection of breeding stock is good, but the after-manipulation is ruinous. He says, "When they swarm, remove to a new stand the hive from which the swarm issued. Hive the swarm on the old stand, giving it, say, three combs of brood from the old stock." First, if I were going to use the queen-cells (swarming-cells) from a hive from which a swarm had issued I would add bees to it rather than move it off the old stand and thus deprive it of the field bees that should return to it. Not satisfied with thus depopulating the cell-building colony, Mr. C. takes three combs of brood from them and gives to the new swarm, and does not even tell us to shake all the bees from these combs back into the parent hive. Not satisfied with this second depletion of the cell-builders' force, he then divides the remainder into three nuclei and keeps them building queen-cells for the next seven days. I would not use a queen-cell from a hive thus moved from the old stand and weakened after swarming, to say nothing of dividing it up, as does Mr. C., and allowing these small nuclei, in their weakened state, to care for queen-cells seven or any number of days. If you desire to use such cells, do not fail to keep

the old hive full of bees, and do not divide it into nuclei until seven or eight days after swarming; then you will have queens that are serviceable, and developed under favorable conditions. These surplus cells can then be removed safely and given to other nuclei, as they will be (as a queen-breeder would say) ripe. In this condition they can be handled with much less damage to the inmates. The owner of half a dozen colonies can use this method as well as the extensive breeder. The latter, however, necessarily does not depend on swarming-cells. An *unripe queen-cell* should never be placed in a nucleus. I often have the young queens emerging from cells while distributing them to nuclei. These queens have had the benefit of very strong colonies from start to finish. Long experience has taught me that this method develops the best queens.

### CLIPPING QUEENS' WINGS.

Lean the comb against the hive; catch the queen's wing between the thumb and index finger of the left hand; place the point of the scissors against the index finger, with the wing between the blades, and cut. The queen clings to the comb, and there is no danger of amputating the leg.

TWO QUEENS IN A TEN-FRAME HIVE WITH A  
SOLID DIVISION-BOARD, PAGE 372.

For many years I have used a thin division-board in ten-frame hives in early spring to secure an abundance of nurse bees for building queen-cells. A zinc excluder is fastened to the top of the division-board by small bent wire nails so it can be removed at will, and brood from the brood-chamber exchanged for combs from which the brood has mostly hatched in the super. This gives practically ten combs for each queen, and at the same time keeps the increase in one two-story hive, giving the best conditions for cell-building in a super *a la* Doolittle. After the season is so far advanced that one queen and her bees can keep the proper strength for this work, one queen and the division-board are removed. I have lost but one queen by this method, and this was from a defect in the division-board. When first prepared I place one sheet of newspaper on the excluder; punch a few small holes through it so that a few bees can come up from either side of the division-board. Next I select good worker combs partly filled with honey; bruise some of the cappings and place them in the super. The bees will remove the honey from the bruised combs to the lower chamber, working peacefully together. The paper will soon be cut away by the bees, and it will be practically one colony of bees, and the exchange of combs can be commenced and queen-cells given them, after having been started by either of the methods practiced by queen-breeders. I can see no reason for wishing to keep two or more queens in a ten-frame hive after the season has so far advanced that colonies should be practically strong, unless it should be that there were some colonies too weak to work in supers. In that case the two queens can remain, and their progeny store honey in the same super. Any queen unable to keep a ten-frame hive full of brood should have her head pinched.

## FROM DIFFERENT FIELDS

### YOUNG BEES NOT ABLE TO FIND THEIR WAY BACK TO THE HIVES.

[In our Feb. 15th issue there arose a little discussion between Dr. Miller and the editor. The question came up over the use of the Miller bee-escape placed on a pile of supers that had been removed from their respective hives with the bees in them, with a bee-escape on top. We took the position that, when such supers were remote from their hives, there would be young bees that could not fly and would be lost. Dr. Miller raised the point whether such young bees would ever desert the brood and go above. At any rate he had practiced the plan much, and had experienced no such loss. Not being entirely sure of our ground we called for reports. The only one we have received sustains the editor, and here it is.—Ed.]

In your note on page 200 of Feb. 15th you ask for an expression from subscribers in regard to bees being lost from supers when taken away from the hives before bees are out. Last summer I took two supers off before the bees had all gone down; and, it being time to go to work, I took them to my shop, about ten rods away, where I placed them on an escape-board, gave them a little smoke to start them, and left them just outside. The bees came out and flew around as if lost, and finally settled down in little bunches; and those that I did not carry back died. I think that all the old bees had gone down through the escape before I took the supers from the hive; and as the young ones had never located the hive they were lost.

ALBERT I. MILLS.

Ignacio, Colo.

[One swallow doesn't make a summer, and we should be glad to hear from others. The question is important; for if Dr. Miller's way is wasteful of bee life we should know it. If it is not, it is a convenient method to use at times. In the multitude of counselors there is wisdom. So, bee-keeping friends, especially those who know, we should like to hear from you. The editor is not particularly anxious to be "vin licated" at the expense of truth; but if he is right he would like the satisfaction of telling Dr. Miller, "I told you so."—Ed.]

### REMOVING BEES FROM BUILDINGS WITHOUT DOING ANY CUTTING.

My near neighbor had some bees in his house for several years. They entered over the front porch, where the "L" joins the main part of the house. I thought I would give them a trial last spring, so I stopped all places of entrance except one. Over that I put a bee-escape. Up against this, on May 8, I put a hive with one frame containing some brood, larvæ, and eggs. May 11th I took the hive home, about 200 feet, and removed the bee-escape. A few of the bees returned, but enough stood by the hive to build up into a strong colony. May 16th I put a second hive up against the bee-escapes, and captured a much larger swarm which I removed May 31. June 8th I put on the escape again, and put up the third hive, captured another good swarm, which I took off July 1 and moved them three miles out of town. These three swarms have all built up strong, and the last two made some surplus honey.

All three swarms had two frames of comb, and only starters in the other six frames. In each

hive the combs have all been drawn out and filled with stores for winter.

But the end was not reached yet. There were still some bees left in the house. July 8th I put on the bee-escape, set hive No. 4, and soon had a lot of bees, and they drew out the comb and filled it with brood and honey. I left the bee-escape on for seven weeks. I thought I would get them all this time. I then took it off and left the hive so that the bees could go in and bring out the honey if there was any in the house.

After awhile something happened up there. A war was on, and in a few days I found the hive did not contain half the bees. I could not find a queen, and brood was wanting. I think there was 30 to 40 lbs. of honey in the hive. I ordered a queen to put in, and on going to the hive about a week after I found the bees nearly all gone, and the honey all transferred to some other place. It is possible they went back into the house. If so I will give them another trial this spring.

GEO. H. EASTMAN.

Storm Lake, Iowa.

[Our correspondent should have trapped the bees out into one hive, or, at most, two. Using so many different hives entailed a large amount of work, which apparently did not succeed in the end in accomplishing the main object—to get all the bees out of the house. It is very evident that the bees from the last hive went back to their old quarters. If this hive had been removed to a location two miles away there would have been no returning.—Ed.]

### EARLY OR LATE TAKING OF BEES OUT OF THE CELLAR; SOME INTERESTING FACTS THAT SPEAK FOR THEMSELVES.

Last Thursday, April 23d, was cold in the morning (about 35), and it got warm rapidly. At noon the thermometer stood at 70, and I said to myself, "I almost know Mr. Kinyon will be working with his bees, and after dinner I will go up and see him."

After dinner I got into the auto, and in about twenty minutes I was at his place, and, sure enough, he was working with the bees with his brother. He halloed to me and said:

"I will be through with this hive in a few moments."

He said he had just begun working with them, and added that he would get me a veil. He tied one around my hat, and then we sallied forth to see what condition the bees were in. He said, "Here, take this cover for a seat." He then opened a hive, remarking as he did so, "These bees, the first two rows, were taken out of the cellar March 16th. After we go through these we will go through two rows that were taken out April 16th, and I want you to note the difference."

The first hive opened had considerable brood, and was doing nicely. Hive after hive was opened, and we found them in pretty good condition so far as brood, strength, and honey on hand were concerned. We soon got over the two rows. "Now we will look over those taken out April 16th."

We opened the first hive, and I immediately remarked, "Why, they haven't any brood."

Mr. Kinyon said, "I guess they are queenless. No, here is a small patch."

We kept on through these two rows and found each colony had a very small lot of brood. Most of them had no sealed brood.

"Well," I said, "it looks as though the first lot of bees were a good lot ahead of the April 16th lot. Those last set out *may* go ahead of those taken out March 16th."

"Not so," said Mr. Kinyon. "The early lot has brood hatching, and in the course of two or three weeks will be very strong. Those taken out April 16th will, on the contrary, get weaker for the next two or three weeks."

"You are correct in this," said I, "and it will be best to conclude that bees taken out by April 1st will do the best."

Mr. Kinyon then said, "Make it the last week in March."

I said, "Yes, we will say the last week in March if the weather is right."

He then told me that he had worked for Mr. P. H. Elwood, and he made a practice of taking out some early and some late, and found after a course of a few years that those taken out early did the best. Mr. Elwood now takes out his bees as early as possible. In this I think he is correct after being with Mr. Kinyon and seeing the difference in the amount of brood in the different lots.

F. A. SALISBURY.

Syracuse, N. Y., April 27, 1908.

BEES THAT CAP THE COMBS "WATERY" ARE HUSTLERS; SHALL WE PINCH THE HEADS OF QUEENS PRODUCING SUCH BEES?

I read with no little interest the article from the pen of Mr. J. A. Crane, page 429, on breeding of queens; and, as you request expression of opinion of your readers regarding a particular point raised by him, I wish to say that I do not think I could have expressed my own ideas on the entire subject better than he has done—especially that regarding "greasy" sections, to which you refer. I have written up the matter of greasy or watery sections, as they are sometimes called, several times since my bee-keeping experience began; and but few of the "old heads" in the business seemed to take kindly to my theory. It is gratifying to me to read an article from one who has had long experience in the business coinciding with me in this matter. I have had several queens whose bees capped their honey "greasy," and they were all hustlers. The hive during the busy season was kept full of workers, and hot. Such a queen is always a prolific one. When the question of disposing of such a queen has been considered, and advice has been given to "pinch her head," I have said, "No, do not do that, but send her to me. She is probably the best queen in the yard."

Evanston, Ill.

WM. W. WHITNEY.

PROPER WEIGHT OF FOUNDATION FOR THE SPLIT-SECTION PLAN.

I have received several inquiries from beekeepers who wish to try my method of putting foundation in sections, asking what weight to use. Perhaps I can best answer the question by telling them what *not* to use, since I have as yet used only the extra thin in sections; however, owing to the trouble I have had with it for the past two or three seasons, I shall not use it again. I

don't yet know whether I shall prefer the thin or the medium brood.

The trouble with the extra thin seems to be that there is not enough side wall, and the bees will often remove what little there is, leaving a smooth sheet of wax; and I find an occasional section with one side full of honey and only a plain sheet of wax on the other.

Since I do not find this in frames where heavy foundation is used in the same super, I lay it to the foundation; therefore I would advise beginners to use nothing lighter than thin in full sheets.

J. E. HAND.

Birmingham, Ohio.

[Medium or even light-brood foundation would, in our judgment, be altogether too heavy for use in sections. Nothing heavier than thin super should be used. We would urge the use of extra thin as being not only cheaper, but causing less of midrib in the comb. Mr. Hand's experience, to the effect that the bees will remove the side wall of this light weight, would seem to be very unusual, or at least we do not remember to have read of any reports of it before. We should be glad to hear briefly from a large number of our subscribers on this point.

Objection on the part of consumers has been raised, that comb honey of to-day has too much of midrib or "gob," and we believe that beekeepers should, so far as possible, use the extra thin. This is an important subject that will bear discussion.—ED.]

THE MASSACHUSETTS SOCIETY OF BEE-KEEPERS; WHY ONE SHOULD REAR HIS QUEENS.

The fifth regular meeting of the Massachusetts Society of Bee-keepers was held in the Ford Building, March 7, with 43 members present. Our speaker was Mr. Chas. S. Blake, of Ashby, Mass. He gave a very instructive paper on queen-raising among small bee-keepers. He laid particular stress upon the fact that, by great care in selecting, the stock can be better controlled than by introducing queens from abroad. He considered that a person with only ten colonies could raise his own queens with profit. Various devices were shown us, by means of which at slight expense the queen-cells could be arranged, and nursery-cages used; also by which an ordinary eight-frame hive could be divided into four compartments for nuclei.

Mr. Blake announced to us that foul brood had made its appearance in Brookfield, Marlboro, and Leominster, and warned us to be on the lookout.

The death of Mr. Henry Alley, of Wenham, Mass., a veteran bee-keeper, and breeder of the Adel queens, and an authority on the subject of bees, was announced. The meeting closed at 4:15 P. M.

Belmont, Mass. •

X. A. REED.

SPLIT SECTIONS USED AND NOT LIKED; CARTONS FOR COMB HONEY; BEES ROBBING OR HELPING EACH OTHER.

I have used split sections, and the editor, in his comments some time ago on such sections, spoke for me. The split section is all right until taken from the hive. I have but one life to live, and I do not want to take part of that in explaining to people why I took that nice white polish-

ed section and made that ungainly saw-cut through it, and then plastered the crack up with beeswax.

The proper covering for a section of honey is the pasteboard carton; and if this has a sheet of mica (isinglass) in the front it renders it transparent enough to show the honey and its grade to good advantage.

On page 228 our German friend says, "If a strong colony stands next to a weak one during a rich honey-flow, and succeeds in filling its own chamber to overflowing, it happens now and then that the strong colony, having no further room, will help to fill the hive of the weak one in the most peaceful way." Bees may do that way in Germany, and perhaps some of your readers may be able to vouch for the same thing here, but I can not. I have handled bees for 25 years, and find them more prone to rob each other than to help. I wish we *did* have a race of bees that would equalize the stores of the whole apiary. It would save lots of work on the apiarist's part, as we would then know the condition of each colony as regards stores without having to look it over.

BERTHA M. TIMONEY.

Smyrna, Me.

#### HOW TO LABEL HONEY PRODUCED FROM TWO OR MORE SOURCES.

Will you please give me your opinion whether we should lay ourselves open to infringing the pure-food laws by marking our shipping-cases "Pure alfalfa comb honey" when only a portion of the honey is from alfalfa, and by far the larger part from melilotus.

H. F. HART.

Allenville, Ala.

[Under the law you would have to label the honey "Pure alfalfa and melilotus honey." If, on the other hand, the honey was largely alfalfa, enough so to give distinctly the alfalfa taste, we would see no objection to calling it alfalfa. It is the *spirit* of the law, not the exact letter of it, that should be observed. If a honey contained white clover, sweet clover, and alfalfa, it would be proper to call it a "clover" because all three are clovers. So long as we do not misrepresent on the labels we do not violate the national law. —Ed.]

#### MATURE BEES DYING IN THE SPRING.

I have nearly 200 hives of bees, and have always had good luck until this spring. About ten days ago one hive became diseased. The bees would drag a great many out. It seems they are paralyzed. Now, I have about seven hives affected. What can or should I do to prevent spreading? Inside the hive seems healthy; they have a good queen and brood, but, of course, they will soon dwindle away.

Dover, Ky.

D. F. WEAVER.

[This case may be similar to the one described by A. L. Youngman on page 1568, 1907. Although the trouble in the two instances was not noticed at the same time of the year, possibly the other conditions might be enough alike to bring about the same result. On page 233, this year, Mr. Wm. McEvoy lays the blame on the honey, and it is just possible that the honey is to blame in this case. If any spraying has been done during fruit-bloom in the locality it would look like a clear case of poisoning. At the last convention

of the Northern Michigan Bee-keepers' Association quite a number reported cases somewhat like this, and there seemed to be no explanation for it. Since the mature bees only are affected, it would seem that the trouble must be similar to some such disease as bee-paralysis, dysentery, or poisoning. Who has had experience that will throw some light on the matter? See the following from Mr. Allen:—Ed.]

#### PARALYSIS OR DYSENTERY.

In the Dec 15th issue is a letter from Mr. A. L. Youngman, headed "Paralysis or Dysentery." I had the same trouble start in on three of my hives here last fall. I started in to feed them, Sept. 7, after I had all supers off. By the 14th I was through feeding. I closed the entrance to about 6 inches by  $\frac{3}{8}$ , and then the bees commenced to die. They would crawl out on the board, bloated as if they were ready to burst open. This kept up for about two weeks, and half of the workers from three of the strongest hives I had were dead. On opening some of them there was a thick brown paste, and near the body there would be a little water. I had these hives covered over with paper and carpet. I thought my bees were too warm, so I removed all carpet and paper, and opened up the full entrance, making it  $\frac{3}{8}$  by the width of the ten-frame hive. Three days after, there were no more bloated bees on the board.

As Mr. Youngman stated in his letter that, about the time of his trouble, there was a spell of two weeks of bad weather, it may have been very wet and warm in the hives, and that started the trouble. He did not state if he had  $\frac{3}{8}$  or  $\frac{7}{8}$  entrance

GEO. H. ALLEN.

South Boston, Mass.

#### GOOD YIELDS WITH RAPID INCREASE, BY AN AMATEUR.

In 1903 we started with 11 colonies in Dove-tailed hives. We increased to 27, and our surplus was 136 lbs. per colony. In 1904 we increased to 62, and surplus was 127 lbs. per colony. In 1905 we started in the spring with 51 colonies, having lost 11 during the winter. We increased to 135, and our surplus was 66 $\frac{1}{2}$  lbs. per colony. In 1906 we increased to 252, and our surplus was 62 lbs. per colony. In 1907, the season just passed, we increased to 300, and our surplus was 88 lbs. per colony. We raise all our own queens. When I say *we* I mean my wife and three daughters, ranging in age from 7 to 17, and myself, we doing all the work. The 1907 crop brought \$1742. Our expenses were \$635.00, leaving a profit of \$1107.00. We do not expect to do so well every year, as that was a favorable season.

Maxwell, Texas.

M. E. VAN EVERY.

#### THE HONEY-FLOW IN MANATEE CO., FLORIDA.

We have been having the heaviest honey-flow from palmetto for ten years. One colony on scales brought in 50 lbs. in four days, and 80 lbs. in ten days. I expect 20,000 to 30,000 lbs. I have extracted 13,000 lbs. now, and am just starting on another round.

E. B. ROOD.

Bradentown, Fla., May 15.

# NOTES OF TRAVEL

BY A. I. ROOT

At the close of our Thursday-evening prayer-meeting somebody nominated A. I. Root as delegate to the Congregational conference in the neighboring town of Wellington. Well, we have been having a lot of rainy days. We bee-keepers notice it because we are so anxious to have favorable weather for the bees to work on fruit-bloom. By the way, if there is any one season of the year more than another that gives me animation and inspiration it is the time of fruit-bloom.

While the conference was held only twenty miles away, to go by rail would necessitate a roundabout trip. Owing to the bad roads my automobile had not once been out of town; and when Ernest learned that I was going to take my chances with my auto he protested that I would get stuck in the mud, and have breakdowns, etc. Instead of arguing the case with him, however, I slipped off without his knowing it. Truly the roads *were* bad. Had the machine not been overhauled, every thing screwed up tight, and prepared for the rough-and-tumble trip, it would not have stood the racket. Another thing, when I undertake a difficult trip like this I take off the top, the mud-guards, back seat, and, in fact, get rid of every pound of superfluous weight. Had the roads been good I would have taken our pastor along; but as it had rained the day before, I told him he had better not risk my kind of transportation. As it was, I found several places where the roads were so soft that, had I not managed skillfully, my machine would have gone down to the hubs; but by backing up, and then going ahead, and repeating the operation several times, I managed to get up momentum enough to climb out of the mire on top of the partly dried crust. I allowed two hours for the twenty miles under the circumstances. I got up to the church just about fifteen minutes before the opening of the meeting. I can not take space here to tell you of the excellent addresses we had. Notwithstanding I was intensely interested in all of them, I found it a rather severe task on my strength to listen to five good addresses, one after another, without any intermission. I am afraid I actually longed to get back into that automobile, notwithstanding the bad and muddy roads.

I found by the program that the session did not open on the second day before ten o'clock. I also knew there was one of the finest poultry-farms in Ohio not many miles away; and so between three and four o'clock next morning, just as soon as there was a glimpse of daylight, I was off with my automobile again. By the way, I have always enjoyed getting up in the morning in springtime, before anybody else is in sight. At such times I feel something like Robinson Crusoe in the old poem:

I am monarch of all I survey,  
My right there is none to dispute  
From the center around to the sea  
I am lord of the fowl and the brute.

Yes, I used to enjoy taking a walk on foot, hours before anybody else was stirring. Later I told you about my early morning bicycle rides;

but I have never found any thing to compare with an automobile ride early in the morning, when the fruit-trees are just coming into bloom. There is one wonderful advantage; the roads are clear of all vehicles; and this is especially important when there is only a narrow track of good road. On this morning especially I let the little Olds auto go like a young colt; in fact, I became so intoxicated with the surroundings and the beautiful workings of the machine that I forgot to watch the glass cup containing the lubricating oil. The oil gave out before I knew it, and the water in the tank was boiling furiously as a consequence. I had to walk quite a piece to a farmer's to get a pail of water. When I went to fill up the oil-cup I found the little pump that we use for filling it had been left at home. How much trouble a little forgetfulness on the part of elderly people like myself sometimes occasions!

Not long after my mishap with the automobile I happened to glance at a farmer's home just ahead of me, and was astonished to see several long rows of chaff hives—perhaps over a hundred in all. I said to myself, "Why, how in the world does it happen that here is a bee-keeper with all these nice hives in this locality, and I did not know any thing about it?" And then as I began to take in the surroundings, things began to look familiar, and I said, "Why, this is Dan White's place as sure as I live." It was still early in the morning, and Mrs. White informed me that "Dan" was somewhere in the back yard. When I explained that my time was very limited, and that I would have to hurry off, friend White said, "Now, Mr. Root, you certainly must stop long enough to go and see my strawberry-patch."

"And are you still growing Gandies, as you used to do?"

"Come and see."

He was soon by my side, and we ran down along the railroad for perhaps a quarter of a mile, and then got over into a field, across a beautiful patch of clover indicating the fertility of the soil; and then we found the Gandy strawberries just showing their beautiful green leaves through the straw mulching. There were two acres in the field, and another field nearly as large right alongside had been carefully prepared and marked out for setting out plants. The straw mulching was not yet disturbed except what disturbance the wind had made during the winter. In some places there was a little too much straw, and in others not quite enough. Mr. White said he would have to get right at it and go over the field carefully.

"Friend W., have you got a man in your employ who will take off just enough straw and not too much, and put on just enough where it is needed somewhere else, and not too much?"

"No, Mr. Root, I have not got such a man, and I do not know where to find one. I am going over that two-acre field, and do every bit of it myself."

Some years ago the folks at our Ohio experiment station at Wooster told me the Gandy strawberry was all right, and that it was about the handsomest and best-flavored strawberry in the world, but they added that it did not bear enough berries. Now, Dan White, after years of experience, has got hold of the secret of making it bear enough berries to pay. He sold his

whole crop last season to Chandler & Rudd, of Cleveland, at an average price of 15 cents per quart, and this at a time when ordinary berries were bringing only from 8 to 10. To do this he has carefully trained pickers. The berries are all assorted; but he says the small quantity of culls cuts a very small figure. He sells those around home for what he can get. Now, that two-acre field was as free from weeds as the small patch in your garden. If I am correct, the ground is well underdrained. Besides this, I judged by the looks of the creek that ran along adjoining the ground that there is a gravelly subsoil there. This piece of ground was originally too wet for strawberries or for any thing else. Friend White had, at considerable expense, had the stream straightened and cut down low enough to get ample and perfect drainage for his strawberry-garden. In years past he grew a great many red raspberries; but now he has concentrated his attention on Gandy strawberries and almost nothing else; in fact, he said that one reason why so many of those nice-looking chaff hives had no bees in them at present was because he was putting so much of his energy into the strawberries. There you see it again, friends. Where a man settles right down on one thing, and gives it his undivided attention, he is enabled to astonish the neighbors and perhaps the outside world with the possibilities along that line, even if it should be so simple a thing as strawberries, and just one perfect variety, the Gandy. If I am correct, he has no other strawberry at present on his farm.

I had planned to get back in time for the opening of the conference; but letting the oil get out hindered me nearly an hour; and letting the machine get almost red-hot necessitated going to a repair-shop. This took more time; but while I was giving directions for repairs somebody put his hand on my shoulder. It was my good friend Charles McClave, proprietor of the Linwood poultry-yard. Now let me digress a little:

I have been many times greatly disappointed when visiting poultry establishments. Yes, some of them costing many thousands of dollars were not, to my mind, pleasant to look at. I suppose it is almost impossible to keep poultry-houses tidy and attractive at all times. Chickens of all ages are fearfully heedless and careless of appearances. By the way, I am wondering if somebody will not eventually give us a poultry-house that will cost us so little we can afford to burn it up every little while and get a new one; and I think we might at least have hens' nests that we can burn up say once a month or two, and get new ones in their place. Well, perhaps poultry-houses can not be kept as tidy as Mrs. Root keeps her kitchen, for instance; but I am sure there is no need of having poultry-yards destitute of every thing green, and looking so untidy that you want to get away from them as soon as possible.

Now, keeping this in mind let me tell you that the Linwood poultry-farm, containing 165 acres, satisfied me in one respect at least. The numerous yards were all covered with beautiful green grass. The number of fowls, if I remember correctly, was not too great in any one yard to keep the grass down. Now, this may be rather expensive business; but Mr. McClave has, perhaps, some of the highest-scoring birds in the world; and his stock is worth so much money that it

would be ridiculous to keep it in cramped quarters. I was so much pleased with the grassy runs that I wrote and asked him about it. Here is what he says:

The grass in our poultry-yards is blue grass and timothy mixed. Regarding the number of fowls that can be kept on an acre, I will state that, if well seeded before the fowls are penned, I think we could keep 100. It might be necessary to keep them off early in the spring until the ground settles, as they dig it over pretty thoroughly hunting angleworms, which would destroy the grass. We have always endeavored to keep all our yards covered with grass at all times. It is much better for the fowls, and gives the yards a better appearance. Growing vegetation also takes up any decomposed matter which may be scattered over the ground.

CHAS. McCLAVE.

New London, Ohio, May 5.

I did not have time to look over all the different breeds of fowls. I believe he endeavors to keep almost every thing that is called for. What interested me most just then was the ducks, geese, and turkeys; and I confess I was not aware before that the wild geese and wild ducks of America were kept anywhere in a state of domestication. I have all my life been curious in regard to the wild geese that fly over our heads; and when we went to the back part of the farm where he has such a poultry-yard, comprising about *forty acres* of timber kept mainly for this flock of wild geese, I was delighted you may be sure. If these American wild geese are not the handsomest fowls in the world they were to me just then the most interesting. The yard is surrounded by a very high wire fence, and the wild geese have the last joint of one wing clipped off while they are young. This prevents them from getting over the fence, but in no way impairs their beauty. These beautiful fowls, like the human family (or at least most of our own race) object to polygamy. Each gander chooses his own particular goose, and, if I am correct, sticks to her through life. I hope so, any way. When we came near them the gander uttered a peculiar note of protest. I did not understand the language, but I took it that he and his good wife were not particularly glad to see us. I think friend McClave says he has kept wild geese for about thirty years. The first one he got was wounded in the wing by a hunter; then by advertising he found a mate for this goose and succeeded in raising some goslings. Then he advertised for wild geese caught alive, and finally got quite a flock. He is buying and selling wild geese all the time. Said I, "Now, friend McClave, I want you to tell me how many eggs these native wild geese and ducks lay, compared with our modern improved breeds. Do the wild fowls ever come anywhere near 200 eggs a year?"

"Oh! no, no, Mr. Root; nothing like it. Why, if I get two or more settings in a year from a pair of wild geese I do exceedingly well."

In the first place, the goose lays only five or six eggs when she wants to sit; and one has to be extremely careful about meddling with the eggs or nest, or the fowls will be frightened away and the hatch be lost.

"Just a few days ago some schoolchildren got over where I keep my flock of wild geese," Mr. M. continued, "and carried away seven eggs that were about ready to hatch. Those eggs were worth more than a dollar apiece to me, and yet they were of no kind of use to those schoolchildren."

Perhaps I should add that that patch of forty

acres has a little flock of valuable sheep on it, as they do not interfere with the geese. He had also a very pretty flock of buff Orpingtons in the same yard. The wild ducks were also especially pleasing to me; but I was in such a hurry to get back to the conference that I did not see them as much as I would have liked. If I remember correctly, they are allowed to fly; but they have been so well trained to come back to their regular feeding-place that they seldom get lost. Besides the wild ducks and geese there are geese and ducks and turkeys from all over the world; and not only are full-grown fowls offered for sale, but eggs for hatching. Instead of an hour or two one ought to have a whole day to look over the wonderful things to be seen at the Linwood poultry-yards, New London, Ohio.

I told the man who repaired my machine that, inasmuch as I was a delegate to the Wellington conference, I would have to have the auto at a certain hour, and it was already time for me to start out when I got around. By the way, it seems to me there is a great opening for bright young mechanics in the way of repairing automobiles. When I told this man, Mr. Chas. Hartman, of New London, that my time was quite limited he, at once got right down under the machine, in the dust and dirt; and before he got through, it was not only dust and dirt but dirty water that got almost all over him, for he had to remove the rubber tubing attached to the coils. His charge for doing this work was only 40 cents an hour. He did not get in anything for "extras," and he did not make any part of the machine *worse* instead of better; in fact, I think it never ran nicer as it "galloped" up hill and down toward my Medina home.

I suppose I ought not to tell it; but after all of Ernest's caution to me he took his larger machine (and *heavier*) and followed me, and had to get some farmers to bring rails and pry his machine out of the mud where I got through safely the day before. This is one of the advantages of a light machine after it has been stripped of all extras, and I think it is a *little* advantage too to have a man in the seat who has run the machine more than ten thousand miles, even if he is almost 70 years old. Just one thing more:

The man of age and experience, especially if he is a Christian man, is not so likely to annoy or interrupt the regular and legitimate traffic of horse vehicles on our nation's great highways.

---

## TEMPERANCE

---

Whoso shall offend one of these little ones which believe in me, it were better for him that a millstone were hanged about his neck, and that he were drowned in the depth of the sea.—MATT. 18:6.

More than six months ago, when glancing over the anti-saloon periodicals from different States my eye caught on to a picture of some boys, in the *Missouri Issue* for Sept. 6, 1907. I looked at the picture and read the matter above it and then the matter under the two pictures, and meditated over the matter for a Home paper in our journal. The paper got covered up, however, with others and got out of sight, and so I rather forgot about it. A few days ago, one morning while at breakfast, while reading our daily Bible lesson my

eye struck on the words of our text at the head of this talk, and I recalled the picture that was still lying on my desk somewhere; and for the first time it occurred to me that this text had direct reference to the liquor-traffic, the traffic in cigarettes, or any other business that will lead our people down to death and ruin instead of up toward righteousness and heaven. I hunted up that old scrap in the *Missouri Issue*, and now take pleasure in submitting to you (p. 698) two pictures. What do you think of them? And what do you think of the men who would deliberately teach these boys to drink and swear, and to smoke cigarettes? There is no exaggeration about this, friends. These pictures are of just such boys as you have in your own neighborhood and in your own home. One part of the group is made up, evidently, of the children of well-to-do families. The other group shows some boys who, perhaps, are not so fortunate, or are so considered by the world; but if you had lived as long as I have, and kept your eyes open, you would have found out that the nicely dressed boys are no safer from Satan's wiles than the other ones—sometimes I think they are not as safe; for the boys who have to work for every nickel they have to spend are less likely, as a rule, to use it foolishly. The boys who have plenty of money, and not much to do, are the ones who get into bad habits. Just recall what has happened to some of the boys whose fathers are millionaires. Carnegie says it is a disgrace to *die* rich; and I begin to think it is a misfortune to be *born* rich. The great men of the present day came, as a rule, from the class on the right-hand picture that lies before you.

The brewers and saloon-keepers are already getting desperate because their trade is suffering. They must have constant recruits or their business can not hold up and prosper. Dear me! What an *awful* piece of sarcasm to talk about "prosperity" in connection with any business designed to educate and train those innocent, unsuspecting little chaps in the course that leads down to hell! Boys are full of mischief. Your boys and my boys were and are. If they were not full of mischief, and constantly looking about for fun, and inquiring into the whys and wherefores of things, they would not be "much good." Their little minds are ready to be molded and fashioned. They are ready to take up with any thing that comes along; and when they get started they are, as a rule, full of enthusiasm and push. You may get them interested in bees or chickens, or in a printing-press or a garden, and a thousand other things; but if you do not keep a careful eye on them, and look out, somebody else will get them interested in smoking cigarettes, drinking beer, gambling, and things of that sort. May God be praised that I shall always have the mothers on my side, even if I do not get hold of the fathers. May God hasten the day when our mothers shall have a little more to say in regard to the environments of the home. There may be some fathers, but I trust not many mothers, who will say they can take care of their own children, and other fathers and mothers can take care of theirs. In other words, *whose* boys shall keep the ginmills running, your boy or mine?

While GLEANINGS has had many encouraging words in regard to the stand it has taken in the

temperance crusade, once in a while it gets something from the other side. I suppose you are well aware that we send a printed statement to all of our subscribers when their time runs out, asking them to remit if they wish their journal continued. I am now going to give you a brief letter from one of our subscribers who is not exactly pleased, evidently, with the course GLEANINGS has taken. I will give only the initials of the writer and the name of his State, for I do not wish to be personal:

The d—d local-option law has knocked us out of business, and so we have to cut down expenses.  
Illinois, April 24. J. H. H.

Although this friend asked to have his journal stopped, I am going to mail him one more number, and I want him to look at these pictures. And permit me to say to him, and others who may have their revenue cut off by the recent crusade, something as follows:

"Dear brothers, when you take a look at the picture of those boys, and realize that it is in your power to influence them either in the downward path that leads to ruin or in the straight and narrow path that leads to heaven, can you for a moment think of doing any thing, no matter how much money you may get out of it, that would lead them astray? Are not the words of our opening text the words spoken by God's holy Son — words that bear the stamp of having come from heaven rather than earth? You may get money, it is true; but more than one millionaire has found his money to be a veritable millstone hung about his neck."

Just a few days before I left Florida a wealthy man in our own neighborhood, who got his money in the liquor business, made one of his employees a Christmas present of a jug of whisky. Just think of it! a *jug of whisky* for a Christmas present! Well, this employee, although he had not been much in the habit of attending our Sunday-school at Osprey, on that special Christmas eve he took his wife to the Christmas-tree in that little chapel I have told you about. The poor woman had suffered from sickness and other trials, and was just getting able once more to care for her little family of two. After the Christmas celebration was over, when this man and his family were sound asleep, perhaps a little after midnight, two other drinking men roused them up and demanded the jug of whisky or what remained of it. In the altercation which ensued, the man who received the whisky was shot, and his poor innocent wife was so prostrated by the tragedy on that Christmas morning that she went insane and is now in the asylum, and in a few days later the man of wealth, who presented that jug of whisky to the murdered man, himself committed suicide. That is the sort of Christmas present that that jug of whisky proved to be.

Dear friends, if your former occupation is gone, and you are obliged to turn to something else for a livelihood, can you not thank God for having blocked the way so that you can now engage in something that will be useful to humanity?

Now I want you all to take a look at that picture of the boys once more. Think of teaching these little fellows to smoke cigarettes when the whole wide world agrees in regard to the terrible

damage the habit does to the boys physically as well as mentally. The teachers in our schools are a unit, and I may almost say the same thing of our fathers and mothers, and yet this traffic goes on. Seven States have already prohibited their manufacture and sale. These States are Tennessee, Oklahoma, Indiana, Wisconsin, Nebraska, Washington, and Arkansas. Ohio has once more been defeated in her effort to banish cigarettes. Just one little woman, Miss Lucy Page Gaston, is leading the fight. If you want to write to her, address her at 1119 Woman's Temple, Chicago, Ill.

In a recent letter she sends me the following newspaper clipping:

Probate Judge Samuel L. Black gave the anti-cigarette crusade movement a great impetus Sunday afternoon in a forceful and pointed address delivered at the mass meeting held in the Central Presbyterian church, Columbus. After denouncing the cigarette as the means of ruining more boys than the open saloon, he declared that, if the pending juvenile-court bill passes the legislature, he would at once commence handing out heavy fines and workhouse sentences to the hundreds of Columbus druggists, and poolroom and tobacco-store proprietors, who persist in supplying the young boys with the nefarious "coffin-nails."

"The evil of the cigarette curse lies mainly in the ease with which any youngster in Columbus can secure all the cigarettes he can smoke," said Judge Black. "Very few saloonists will sell liquor to a lad under sixteen. They are afraid to. But youngsters of even the most tender years can purchase their tobacco supply almost anywhere. The resulting havoc is evidenced in our juvenile-court records. It is not fair to punish the boy for smoking. The adult who furnishes the obnoxious weed, and derives a lucrative revenue, is the real culprit. He is the man who is filling our prisons and public institutions. If a good prohibitory measure were passed in Ohio it would not be necessary for a Columbus police judge to parole fifty or a hundred prisoners in order that room may be made for the constantly increasing throng."

Judge Black forcibly illustrated his talk with incidents that came under his notice in the juvenile court and the graver cases brought to his notice as probate judge.

Just think of that, friends. These cigarette manufacturers and venders say in substance, "We do not care a — what becomes of your boys. We are going to have their nickels, if we can get them, as long as the boys have any." If the above are not the exact words they use, it certainly is the spirit of what their actions manifest, and all for a little money. By the way, is it not true that there are a good many of us, and some mothers, perhaps, as well as fathers, who are straining every nerve for nickels and dollars? and yet when we come to die, of what use then is this money or property? And sometimes, even before we come to die, we begin to realize that money does not purchase peace of mind or happiness. I have exhorted you many times lately about laying up treasures in heaven instead of here on earth. Now, is there any other way in this world by which we can more *surely* lay up treasures in *heaven* than by keeping a careful and loving eye over these young boys and girls just growing up, no matter whether they are your children or those of your neighbor? They are God's children, and the responsibility rests on us to look after them and protect them by law as well as lies in our power. See that they are brought into the Sunday-school; that they are taught these precious and wonderful texts out of God's word; that they are properly protected from these demons in human form who would blast their young lives just to obtain a few nickels. In closing I wish to give you one more text:

And whatsoever shall give to drink unto one of these little ones a cup of cold water only, in the name of a disciple, verily I say unto you he shall in no wise lose his reward.—MATT. 10:42

"REJOICE AND BE GLAD."

One of the friends adds, by way of postscript to a kind letter, something that reads as follows. It occurred to me that it would follow nicely the thought expressed in my temperance talk for this issue.

And now let me tell you why I am so exceedingly happy to-night that I can hardly write straight. Our city of about 80,000 inhabitants, after eleven years of rum rule and unbridled license, debauchery, drunkenness, and high-handed devilry that would rival Sodom and Gomorrah in brazen defiance of morality and decency, has gone *no license* by 1678 majority—a flop of 3000 from last year. I feel like throwing up my hat with a baseball yell that would startle the ashes of old Father Matthew. I am sure (and this will interest you) that every Methodist bell in town was rung last night for all it would stand without cracking. Rejoice with us. Next May will see all the snake-factories closed down tight, thanks to Providence, through the Lynn No-license League. We think there are brains and money and push enough behind this movement to make it permanent, and especially hot for law-breakers in the business of wet goods. The city of Worcester ditto. The business of the country is waking up to the fact that drunkenness is an unreliable factor in the marts of trade.

H. Q. STAPLES.

Lynn, Mass., Dec. 14.

## HEALTH NOTES

"DULL AND SLUGGISH."

From T. B. Terry's Health Talk in the *Practical Farmer* for April 25 I clip the following:

Alfred Vieweger, Estellville, N. J., writes: "I am 26 years old, 5 ft. 7 in. tall, and weigh 145. Every week day I have hard work to do for six hours. Dr. Wiley is quoted as saying that a man needs daily on an average an amount of solid food equal to one per cent of his weight. I am perplexed over this. My experience seems to contradict it. According to the doctor I should need about 23 ounces of solid food a day. But I have lived for a week on 9 ounces a day of wheat and butter, and never felt so strong and active before; and then when I tried to come somewhere near what the doctor advised I found myself dull and sluggish—just able to plod along." This report from a young man who is seeking the truth is very pleasing. There are few people who have yet learned just why they feel dull and have a lack of energy at times. By all means, my young friend, follow your own plain experience, but with care to eat proper food, and never mind what Dr. Wiley may or may not have said. If he said it he was wrong for you and for me. For perfect results, eat just as little as you can and hold your normal weight and always feel well, strong, and active. If you eat more, a part of your energy must be used up in taking care of extra food which you did not need, and which partially clogs the fire of life.

Now, friends, the above statement from Mr. Vieweger takes a mighty hold on me, because for the past few years that "dull and sluggish" feeling that he speaks of has been the greatest trial of my life. If I sit down to read a book or paper, and undertake to read a little too long, it comes over me almost overpoweringly; and I have not found any thing but brisk hard work in the open air that will ward it off. Sometimes I think it is the natural outcome of old age; but I hardly think this can be true, because other people keep up their strength and vigor not only up to 70 but sometimes even to 80 years of age. And another thing: I sometimes have spells lasting for several days when I feel almost as well as when I was young. Is it possible that tempting articles of food that I do not need at all are responsible for this feeling of being "just able to plod along," as friend V. expresses it? I have tried taking a light breakfast of some of the breakfast foods, especially the uncooked ones, and I have thought several times I had found out where the trouble was; but after my light breakfast I often get so ravenously hungry by dinner-time, especially when Mrs. Root prepares a tempt-

ing dinner, that it seems almost impossible (I am ashamed to make this confession) to make a stop at the proper time, or to forego entirely the tempting dessert. Yes, dear friends, this is true of your old friend A. I. Root. It seems as if Mrs. Root could not get hold of the idea that I do not really need a good nourishing "square meal." Sometimes she says, "Oh, dear me! what *shall* I get for dinner?" Well, when nobody is to be present, probably, but us two, I say, "Dear Sue, do not get any thing at all. Just give me my bowl of rolled wheat and some butter, and I shall be all right. In fact, I have often *hoped* you would not waste your precious strength in preparing tempting foods for me." I tell her to cook whatever she cares for so far as she herself is concerned, but to let me follow Terry. I think it must be a sort of lack of faith among the women-folks in thinking that we men-folks must have so many elaborate meals with lots of side-dishes to wash and put away, etc. I fear, too, that many of these good wives of ours are afraid of being "out of the fashion." You know women-folks have to dress in a way that thousands of them do not like, because they say they must follow custom or fashion—at least to a certain extent. Well, the younger ones can follow the style if they choose; but I am sure it is not necessary for people as old as Mrs. Root and I to follow all the changes of fashion.

Just one thing more about the "dull and sluggish" feeling. As warm weather comes on I find it a great help to change my heavy woollens for light and loose clothing. Frequent bathing is also a great benefit; and last, but by no means least, fresh cool air every *hour* of the day. May God help us, especially those of us who feel that we are growing old, to learn these important lessons in regard to health, especially along the line of diet. I feel sure that T. B. Terry is on the right track, or pretty nearly so, any way, because I meet people everywhere I go who are rejoicing in better health on a diet of uncooked food. My impression is there are thousands, if we could get their testimony, who are living on "wheat and butter," and not more than "9 ounces" a day at that. While in Florida a very bright and intelligent woman who was visiting in our locality walked to our cottage (two miles) on purpose to tender me her thanks for what T. B. Terry and I had done for her in giving her new life, courage, strength, and happiness. She had been living for a year or more on rolled wheat and pure olive oil. Friend Terry uses the olive oil, a good deal, in place of butter. In that way his diet is entirely vegetable. You may gather from the papers that some of the great athletes of the present day are gaining their strength, and keeping it, on a similar plain simple diet.

In closing, let me remind you once more of the thousands of good women who would be relieved from something that is almost a sort of *slavery* if people generally would adopt the diet recommended in the clipping I have given you. Of course, it takes some *courage* and *self-control* to forego all of these good things we are accustomed to, and which are constantly placed before us. It is true that many people seem to need a certain amount of sweets in their "balanced ration." Well, we bee-keepers have it right at hand, for honey is always *uncooked* food.

## COLDS, GRIP, ETC.

A few days ago Mrs. Root asked if it could be really true that T. B. Terry and his wife never have colds nor the grip, as almost everybody does have all over the North, and to some extent away down in Florida. I told her I would write and see. Below is his reply:

Dear Mr. Root:—No, I do not have colds, grip, nor any other ill. There is no need of having them. I really can't remember when I had my last cold, or ill feeling of any kind. I hardly dare think how perfectly well in every way I am, to say nothing of telling the whole truth, it seems so marvelous. And still it is not. God means we should all be well through a long life. Ignorantly (often, of course) we sin and suffer; that is all. Common ways of living have gradually drifted far from the simple, wholesome, and natural. It was ignorance, from lack of thought, with me once; but the truth has gradually come as I sought earnestly for it. Right here let me say positively that there is no cross about proper living, as people are sure to think, at least for only a short time. I certainly never enjoyed my meals, sleeping, breathing, working, any better than I do now. My wife never has a cold at home. I have been away a week at a time, now and then, and got along all right. Nature allows a reasonable margin. Please notice article this week on strength directly from God. It simply must be so. And next week I am sure you will be deeply interested when you read how GLEANINGS saved a life, beyond question—has saved many, probably, but one special instance is given, and the truth in this case is even stronger than I put it.

T. B. TERRY.

Hudson, O., May 8.

Even though this health talk is getting to be a little long I think the readers of GLEANINGS can afford to read the following, which we clip from Terry's talk in the *Practical Farmer* for May 16:

## BROUGHT BACK FROM DEATH'S DOOR.

A middle-aged reader was troubled with indigestion and constipation by spells for some 20 years. At last he got seriously sick with typhoid fever. The doctor said there was no hope for him, but still he barely pulled through, and was able to sit up for a little after a few weeks. But his troubles were not over. Nothing could be found for him to eat that would not distress his stomach. He seemed unable to digest any thing. Food just lay in his stomach and decayed until it looked as though he must starve to death. Years ago my mother slowly starved to death in just this way. It was terrible, but we did not know how to save her. She had medicine and advice from the best doctors in Detroit. Now read our friend's words, exactly as written: "One day I happened to look into Mr. Root's bee-journal, GLEANINGS, and saw an article telling what you ate, copied from *The Practical Farmer*. I read it over at least a dozen times. I was so deeply interested. A little courage came back, and I thought that possibly there was a chance for me to live yet. I began eating a small amount of dry flaked wheat, uncooked, with olive oil and fruit, about 8 A.M.; then nut meats and fruit at 3 P.M., all most thoroughly chewed, and with much water drank between meals. I never before saw any thing like the change that took place. In one week I was much better in every way. In two months I was strong, and doing my work again. I can not express in words my gratitude to *The Practical Farmer*, Mr. Root, and yourself." This is from a private letter, but it is far too valuable to throw away. I am sure this good friend will pardon me for making the main facts public, so long as names have not been mentioned.

## HIGH-PRESSURE GARDENING

A. I. ROOT

THAT BIG CELERY STORY—SEE PAGE 511.

Well, friends, I have got some high-pressure gardening this time, "sure thing," as my colored boy Charley puts it. Just turn back to pages 566 and 567, May 1, and look at the pictures of that celery-farm of five acres, and now read the brief letter I succeeded in getting from friend Latimer, below:

Dear Friend Root:—I am very sorry I was not at the farm the day you were out to see it. I had gone to the depot to ship a car of celery at the time you were there, and did not find out that you

intended writing up the farm until you had done so, although you seem to have gotten every thing down as it was, with two or three exceptions. One is my name being T. L. Latimer instead of C. L. Latimer; and another, you say "I have reason to think he employs at least one or more expert men who know all about the business." The fact is, I did not have a man who ever tried to raise a celery crop in his place, on the farm at any time during crop season, including myself. I never tried to raise any vegetables until I came to Manatee Co., Fla., a little over a year ago.

Now in regard to marketing the crop, returns, and so on, that you ask me for. I will state that returns are not all in yet, having just shipped the last car this week, but may say the first acre netted over \$1800; the others did not do that well, on account of the very dry spell of weather you spoke of in your journal when you were here, it being broken only this week by a 4-inch down-pour of rain, the day I finished getting out the last car. While I kept it watered with artesian water the country around was very dry, and it affects it to some extent. And then prices were not so good toward the last. On the whole I did a good business—far better than I expected. On the first seven rows, that were 300 feet long, I cut 167 crates that netted \$429.67, or over \$61.00 per row. The rest of the celery was just as good, but I did not get as good prices for it.

We hope to have you back with us when Jack Frost comes again in the North, and we hope to get better acquainted with you.

There is a great temperance rally to-morrow just across the river at Palmetto, where a great revival has been going on for two weeks; and the evangelist, Mr. Bridges, starts one here next week that is destined to do great good in this town.

Bradentown, Fla., April 12.

T. L. LATIMER.

The above is simply astounding. If I did not know the man and had not seen his celery and talked with his eighteen-year-old boy, I might find it hard to believe, myself. We who are "old and wise" have been saying right along that one can not hope to succeed in any business without practical experience. You must commence slowly and build up gradually. Well, that is good advice for most of the world; but this time one man and his eight children (do not forget about the *eight children*, I beg of you) went into a new region—in fact, into a tropical climate where they were entirely unacquainted with any thing or anybody, and actually worked up in a little over one year what I have been telling you. There is another secret to it besides the family of eight children, and I have purposely let you into it by leaving on the concluding paragraph of his kind letter. He is a man who does not drink, and never did drink, and his family follow him; and I gather, too, that he is never so busy in pushing his business but that he can keep track of it and be on hand when a great revival is under way. May the Lord be praised for such men. And this is not all of it, either. May the Lord be praised for the good woman who has taken charge of that family of eight children, and who stands back of brother Latimer for righteousness, temperance, and purity.

Later.—After dictating what I did in the above, my conscience began to trouble me somewhat. I was afraid that there would be many who would feel sure they could do something like what friend Latimer has done, and then would be sorely disappointed. Let me tell you, by way of caution, that all over Florida there are deserted homes, gardens, and fields where somebody has wasted a lot of money, and yet made only a failure. New comers in Manatee Co. many times say, "Why, where are your nice-looking gardens and wonderful crops?" And I confess I have made a lot of apologies and excuses; but when I take them over to my neighbor Rood's and let them see with their own eyes the possibilities of that region they have to admit all that has been told them. Then comes the question, "Why should so many fail when only a

few men here and there succeed?" I do not know, unless it is because so many go down there with a sort of idea that they can get a living in Manatee Co. without work. It is not true of that region nor of any other that I have ever visited.

#### CELERY VERSUS WHEAT.

The following, clipped from a letter written to a brother of the writer, "Stenog," brings out one point very plainly:

I like to look at the pictures in GLEANINGS. The one of the five acres of celery, for which \$5000 was refused, makes the wheat-farms of Ohio seem sick. If five acres of wheat brought \$100 it was considered a good crop. Moral—raise more celery and less of something else. F. J. ROOT.

545 North Grove St., East Orange, N. J., May 12, 1908.

#### SWEET CLOVER AS A FORAGE-PLANT, FROM THE STANDPOINT OF THE FARMER AND STOCK-GROWER.

The two letters which are herewith appended appeared in the *Breeder's Gazette* for May 13. They are self-explanatory. Both tend to show that sweet clover, rightly considered, is one of the most valuable forage-plants we have. It may be added that the *Breeder's Gazette* is the leading paper of its kind in this country. Its large circulation will help to make sweet clover popular, or at least give it fair hearings. W. K. M.

#### SWEET CLOVER A BOON TO ALABAMA.

TO THE GAZETTE.—In your issue of April 29 J. D. Grimes condemns sweet clover (*Melilotus alba*) as a worthless weed, saying stock have to be starved to make them eat it, and that it is very difficult to destroy.

Here in the lime belt of Alabama we consider it one of the most valuable plants we have. Stock, when first placed in a pasture containing it, will not eat it; but they do not come anywhere near starving before they begin to eat. In many pastures there is nothing but melilotus, and these are nearly always the pastures that contain the fattest cattle in the neighborhood. Several of our best farmers depend upon it very largely for hay, cutting it when about 12 to 18 inches high. They say it is nearly as good as alfalfa hay if cut young enough, and their stock is just as fat as the stock that gets alfalfa for roughage. We find it no trouble to kill. One year in corn nearly always about clears the land of it.

As a soil-renovator we think it has no equal on thin lime land. I have seen land that would not make five bushels of corn per acre planted in melilotus for five years and then produce about twenty-five bushels per acre (nearly double the average Alabama yield). This land was pastured a part of the time, and the melilotus was cut for hay the other part.

Some of our most prosperous farmers say if they could have only one of sweet clover and alfalfa they would take the sweet clover. It will grow vigorously, and afford two or three fine cuttings of hay on land so poor that on it alfalfa will not get a start.

#### SHOTES LIKE SWEET CLOVER.

TO THE GAZETTE.—I have been reading the discussion in your journal about sweet clover, with considerable interest. I have had some experience with it. I sowed 20 acres some years ago to alfalfa. The seed contained a liberal percentage of sweet clover. It was a new thing to me, and every one told me that it was a noxious weed and would take the farm, so I decided to plow it up; but before doing so I pastured it one year with cattle. These cattle had the run of an adjoining 20 acres of wild grass. They kept down both alfalfa and sweet clover to the neglect of the wild grass. I plowed it up, and the clover disappeared without any trouble whatever. I do not think it as hard to kill as alfalfa by my means. The only place where it has remained is along the division fence where I have not molested it.

Adjoining this fence I have 30 acres of rye and 10 acres of blue grass on which I have been running 175 shotes. I have noticed that these shotes, which have an abundance of tender rye and blue grass, have kept this clover nipped close to the ground, while on the other side of the fence it is knee high. I should like to sow a field to it. Could you tell me where I could get the seed? J. G. KUNZ.

Hall Co., Neb.

REMARKS.—Write any seedsman whose advertisement has appeared in our columns the past few weeks.—ED. GAZETTE.

#### PAULOWNIA IMPERIALIS.

Our readers will remember our paulownia-tree that grew 16½ feet high the first season, but which, during the winter of 1906, killed down to the ground. Last summer I had given it up for dead; but I had one of my happy surprises along toward the first of June when a great strong shoot shot up close to the base of the old tree. A little later, several shoots started likewise. Of course, I took away all but one. The shoots looked so rank and thrifty that it occurred to me they might be put in damp sand and started as we start cuttings. The plan proved to be a success. Almost every one took root; and last fall, when I started for Florida, I had 25 little trees, one foot and under, planted in a bed of rich ground north of my automobile-house. Before leaving I gave particular directions to one of the men to be sure to mulch the little trees with coarse stable manure before hard freezing; but during my absence it was not attended to, and so I was afraid all of my little trees were winter-killed. At this writing, however, May 1, I am greatly pleased to find almost every one of them alive and sending up great strong shoots.

Now, here is something in regard to this same tree in Mississippi:

I wish grandpa Root could see a paulownia imperialis that is in my back yard. It is 18 inches in diameter, and has been in full bloom since April 1. There is no greater honey-tree than this. The bees work on it from daylight until night drives them in. They even work on it when it is raining, as the flowers hang downward and the nectar does not wash out. R. V. GOSS.

Verona, Miss., April 15.

Many thanks for your report, friend G. I am glad to know you succeed so well with them. I have been wanting to try them in our Florida home, but have not yet got at it. It makes such a tremendous growth in a season here (16½ feet tall with leaves over a yard wide) that it is worth while to plant them, even if they should winter-kill down to the ground nearly every season. In that event, however, of course we could not get any bloom for honey.

I got my first trees of George W. Park, of La-park, Pa. He has not only the trees for sale, but the seed for planting; but he tells us the seed is a week in germinating, and I am under the impression that it requires special treatment. I think propagation by cuttings will be the quickest and surest way.

#### JELLY-MAKER VS. GLUCOSE TRUST.

The Corn Products Co., manufacturers of glucose, is in a controversy, it seems, with makers of low-grade pail jellies, among them the American Preserve Co., of Philadelphia, a chief antagonist to the glucose concern.

The controversy has arisen because the Corn Products Co. has embarked in the business of manufacturing compound jellies which, it is reported, it is selling at prices lower than those made by the regular manufacturers of jellies. The American Preserve Co. resents what it contends is an encroachment upon its business. It charges the Corn Products Co. with entering the jelly-field in order to compel regular jelly-manufacturers to buy their glucose from it.

The Corn Products Co. asserts that it has a perfect right to go into any business that it likes. —*Grocers' Criterion*.

### WE WILL SEND TO YOU FREE.

This handsomely illustrated, fifty-page booklet containing a most interesting description of the famous Manatee section, being a reproduction of a series of articles written by the editor of one of the leading agricultural papers in the United States after a personal investigation by him. The articles were run in serial form in his publication during the last four months, and we have embodied same in an attractive pamphlet, illustrating it with dozens of interesting and instructive scenes from actual life. This handsome piece of literature will be thoroughly enjoyed and worthy of preservation, and will be sent free, together with pamphlet containing a list of properties available in the LAND OF MANATEE upon receipt of five cents in stamps or currency to cover cost of mailing. Our supply of this booklet is limited, and if you want a copy you should not delay, but write at once.

CHICAGO, ILL.

## A NEW HIVE-TOOL

Hitherto we have said very little about our new hive-tool, but after submitting it to some of the foremost bee-keepers of America for their candid opinion—for or against—the universal verdict is that it is a good thing; though it looks like a very simple tool it is very surprising how useful it is to an apiarist. The bent end, for example, is just right for severing Hoffman frames. A slight twist of the wrist does the business without angering the bees, and one's hand is so placed the bees do not see it. For scraping wax and propolis nothing could be finer, and it is better than a chisel, screwdriver, or putty-knife for opening hives. Any bee-keeper will be glad of one in his pocket ready for all occasions. It is made of the finest hardened steel nickel plated.

### Sample Testimonial:

*Mr. Root:—I have been using your nickel-steel hive-tool this spring, and am very much pleased with it. It is the best thing I have tried yet. I, with my helper, have been using tack-pullers heretofore; but this is better because so much stronger. It leaves nothing to be desired except that there should be a hole in it a little nearer the crooked end. I tried to get one drilled but had to give it up—too hard; so I fastened a strap around it to fasten to my pants button.*

# ITALIAN Queens

and bees, and nothing but Italians. An improved superior strain is what QUIRIN-THE-QUEEN-BREEDER raises. Our stock is northern-bred and hardy. We just visited our outyards (all wintered on summer stands), and not a colony is dead to date (March 18). Some hives have lost scarcely a bee, so it appears. BROTHER BEE-KEEPER, how do you like such stock for hardiness? A party up in Maine got 50 nuclei of us several years ago. We just received a letter from him. He is after more of our bees, because last season he got 2200 pounds of honey which sold for 22 cts. per pound. Our stock is well known throughout the United States. Some of the largest yields reported can be traced to our stock. Over 20 years a breeder. Free circular and testimonials. Price of stock as below.

| Prices of Queens before July.           | 1      | 6      | 12     |

## FINEST POSSIBLE BREEDING

BRED BY

**F. J. WARDELL,**  
**UHRICHSVILLE, OHIO, U. S. A.**

After many years' experience as head queen-breeder for The A. I. Root Co., I am now breeding bees at the above address. My stock is equal to any now advertised, and my long experience enables me to judge very accurately the value of any strain. Mine is the celebrated red-clover stock, which has given so much satisfaction to thousands of buyers for a number of years past. If you desire something very select for breeding purposes, write to me, stating your wants, and the same will be supplied. I have no cheap or inferior queens to sell. My prices for the season are as follows:

|                                  | May to June.      |

**Loreauville, Iberia Pa., La.**

# HIGHLAND FARM QUEENS

are the result of years of careful selection and judicious breeding from the best honey-gathering strains of superior long-tongue red-clover Italians in America and Italy. Highland Farm methods will produce perfectly developed, long-lived, and prolific queens. If you want bees that will winter well, build up rapidly in the spring, and roll in the honey Highland Farm queens will produce them. We are now booking orders which will be filled in regular rotation, beginning

May 15. You should get in line by placing your orders early, and avoid the rush of the busy season. Single queens, \$1.00; 6, \$5.00; 12, \$9.00. Safe delivery and satisfaction guaranteed. For further information send your address on a postal card to

**HIGHLAND BEE AND POULTRY FARM,** J. E. HAND, Proprietor, BIRMINGHAM, ERIE CO., O.

Breeding queens of pure Caucasian and Carniolan races—price \$3.00. Order from A. E. Tioff, Expert in Apiculture, with Russian Department of Agriculture, Kieff, Russia. Remit with orders. Correspondence in English.

## SPECIAL NOTICES

BY OUR BUSINESS MANAGER

We have just received a special importation of Italian queens. As other importations are coming we shall be in position to send this year's stock.

We are issuing an appendix to our little book, "Modern Queen-rearing." To those who have already purchased this work we will furnish the appendix for 2 cts. to cover postage.

The Alexander bee-veils are proving to be very satisfactory. They are just the thing for extremely warm weather, because they can be worn without a hat, thus avoiding the unpleasant sweat-line around the forehead where an ordinary hat is worn. Price 72c postpaid.

### FOUNDATION SPLINTS.

Some have been writing Dr. Miller for foundation-splints. He does not have them for sale. We are prepared to furnish them for 10 cts. per 100, 50 cts. per 1000 postpaid, or 40 cts. per 1000 with other goods.

### MISMATED CAUCASIAN QUEENS.

At our south yard we had quite a number of mismated Caucasian queens, a cross between our leather-colored strains of Italians and Caucasians. There may be some who desire this mixture. So long as they last we will furnish them for \$1.00 each. When we run out we will take the liberty of substituting an untested Italian.

### SPECIAL BARGAINS.

We call your attention to a page of special bargains in beekeepers' supplies—some styles not listed at present in our catalog, but which are preferred by some. Most of these goods are offered at reduced prices. If you see any thing you can use, let us have your order and we will see that the goods are promptly forwarded. See our issue for May 1.

### HIVE NUMBERS.

We can supply hive numbers with figures 1½ inches high, printed on tough cardboard, then boiled in paraffine so as not to be injured by the weather. They may be fastened to the hive with tinned tacks. We have them in sets up to 400 numbers. Price \$4.00 per set postpaid, or \$3.50 with other goods; 100 postpaid, \$1.15, or \$1.00 not prepaid; 50 postpaid for 65 cts.; not prepaid, 60 cts.

### BEESWAX.

For good average beeswax shipped before the middle of June we will pay 29 cts. per lb. cash, or 31 in trade delivered here. The season is so far advanced that we make this raise of 1 ct. per lb. for two weeks only, because we do not want to stock up at the close of the season at high prices. If you have any to furnish send it on at once and secure this temporary rise in price.

### CARTONS FOR OUNCE CAKES OF BEESWAX.

We can supply cartons for one-ounce cakes of beeswax, printed with name and address blank, at 35 cts. per 100; 250 for 80 cts.; 500 for \$1.50; 1000 for \$2.75; by mail, 15 cts. per 100 extra. These prices will also include the large carton to contain 32 of the small ones. The complete package weighs 2 lbs., and, when filled, sells to the dealer at \$1.00. They retail the cakes at 5 cts. each. Retinned molds for molding ounce cakes cost 35 cts. per dozen; by mail, 40 cts.; for two-ounce cakes, 40 cts.; by mail, 50. We do not have cartons to fit the two-ounce cakes. To print your name and address on the cartons will add, 250 or less, 50 cts.; 500, 75 cts.; 1000, \$1.00.

### BUSINESS BOOMING.

There has been an unusual amount of swarming this season, and in many localities it has been about a month early. As a result, there has been an unexpected demand for hives. Our capacity has been taxed to its utmost, running 11 hours a day, and still many customers have been disappointed in time of delivery. Such seasons as this emphasize the importance of being forehanded and better prepared for emergencies. Dealers need to carry larger stocks, and bee-keepers should anticipate their needs longer in advance. The foresighted people who order in the fall and early winter, taking time to get their goods, not only at reduced prices, but also in time to prepare them for use in leisure

time ready for use when the season opens, are the fortunate ones in a time like this. We have a good supply of sections ready for prompt shipment, also of most other goods except hives and supers. Some of our dealers have been obliged to hold orders waiting for fresh stock to arrive, and we have been unable to ship as promptly as we should like, because of our inability to turn the goods out fast enough.

### SIMPLEX HONEY-JARS.

The factory people have advised us of a carload of these jars as already on the way to us, with more to follow in due course. By the time your order reaches us we shall have a supply in the warehouse, ready for instant shipment. They will be packed in reshipping-cases of two dozen each, and the price will be \$1.10 per case; six cases, \$6.30.

### NO. 25 HONEY-JARS.

During the past year we have had an unusual amount of trouble with breakage of this jar, even in the reshipping-cases packed with corrugated paper. The breakage occurred either in the porcelain cap or the top rim of the jar where the cap rests. We find we can get this same jar with lacquered tin cap without the center being cut out. This cap is lined with a waxed paper wad which seals tight on the top edge of the jar. This style of cap not only does away with nearly all breakage, but enables us to furnish the jar at a lower price. We are now ready to fill orders. They will be packed as usual, two dozen in reshipping partitioned cases. No. 25 jars, tin cap lined, 90 cts. per case; 6 cases, \$5.10. We can still furnish from stock the usual style of No. 25 with porcelain caps at \$1.10 per case; 6 cases, \$6.30.

### JAPANESE BUCKWHEAT.

The season for sowing buckwheat is at hand. We have a choice lot of seed grown for us last season, which we offer, bags included, at 15 cts. per pound, postpaid; not prepaid, 5 cts. per lb.; 45 cts. per peck; 85 cts. per half-bushel; \$1.50 per bushel; 2 bushels, \$2.50; 10 bushels, \$11.50.

### BEES AND FRUIT.

We have just issued from the press a new booklet by E. R. Root on the subject of the bee-keeper versus fruit-grower, explaining how their interests are mutual; also how the fruit-grower can keep a few bees to pollenate his fruit-trees and not be troubled with swarming. This booklet is nothing more nor less than an address delivered by Mr. Root for the Ohio Agricultural Society, at Columbus, comprising not only horticulturists but pomologists of note throughout Ohio. He introduced a large amount of evidence going to show that there is no direct antagonism between the fruit-grower and the bee-keeper—that their interests are mutual and interrelated, and to a great extent one depends on the other.

While Mr. Root spoke from the standpoint of a bee-keeper, yet he was surprised to learn that the fruit-growers not only indorsed every statement he made, but furnished a considerable amount of additional data.

He also explained how the fruit-grower can keep a few bees to pollenate his trees without swarming, and at the same time secure quite a little crop of honey. All this and more is set forth in the booklet mentioned above. It belongs to our ten-cent library; but in case a bee-keeper is having trouble with his neighbors these booklets will be furnished at a very liberal reduction; namely, \$1.50 per 100 by express or freight with other goods, or \$2.00 per 100 postpaid. Much of the evidence furnished is from fruit-growers of experience and standing; and a few of these booklets distributed in a neighborhood will do much good.

#### SECOND-HAND FOUNDATION-MILLS.

We have to offer the following second-hand foundation-mills in good condition. We shall be pleased to hear from any one interested. To such we can send a small sample of comb foundation representing the kind of work produced by the particular machine you inquire about.

No. 079.—6x2½-inch hex. cell thin-super mill, in very good condition. Price \$12.00.

No. 078.—6x2½-inch hex. cell thin-super mill, in good condition. Price \$12.00.

No. 086.—6x2½-inch hex. cell extra-thin-super mill, in good condition. Price \$12.00.

No. 075.—2x9 hex., very old style, on frame with wood base; in fair condition. Price \$10.00.

No. 085.—2½x6 hex. thin-super mill, in good condition. Price \$12.00.

No. 086.—2½x6 hex. extra-thin-super mill in extra-good condition. Price \$15.00.

No. 096.—2½x10 hex. light-brood mill; almost new; in fine condition. Price \$20.00.

No. 097.—2½x10 hex. light-brood mill; in fine condition. Price \$18.00.

No. 077.—10x2-inch medium-brood round cell, old-style frame, in good condition. Price \$14.00.

No. 092.—6x2½-inch hex. cell extra-thin-super mill, in fine condition. Price \$15.00.

No. 2275.—6x2½-inch hex. cell extra-thin-super mill, in good condition. Price \$13.00.

## Special Notices by A. I. Root

#### "AGE AND EXPERIENCE."

Huber suggested, after reading my *Travels*, on another page, that I failed to mention that, when I reached Medina, I found my steering apparatus badly broken in consequence of running at break-neck speed over roads unfit for travel, notwithstanding my "age and experience." He says I also neglected to say that Ernest carried *five* passengers while I had none.

#### THE NEW TESTAMENT IN SPANISH AND ENGLISH.

After my trip to Cuba, my account of the help received in learning the Spanish language from the above little book caused the sale of a great number of them. You not only learn the language by the use of this book, but you are at the same time getting a knowledge that is of more importance than all the languages on the face of the earth—namely, something about the trip that we are all taking (or ought to be taking) from earth to heaven. Price 25 cts.; by mail, 35.

#### THE ACME HAND POTATO-PLANTER.

As we are now out of the seed-potato business we offer about four dozen Acme potato-planters at a big bargain to close out.

To those who are not familiar with them we will say that this machine makes the holes, and drops and covers all at one operation. Once over the field does the work when the ground is fitted. In the soft soil of Northern Michigan, the great potato region, one expert man or boy will plant two acres in a day. Up there the potatoes are nearly all planted with this little implement. A year ago we offered them at 55 cents each, or three or more at 50 cents each, or one dozen for \$5.25. While they last we will make you a price of 45 cents each, or three planters for \$1.20, or a crate of 12 for \$4.00. If you want them at the above price you had better get your order in before they are gone.

#### "GRAFT" AND THE EXPRESS COMPANIES.

In looking over one of the day-old-chicks catalog which gives the amount of express charges to different points from New Washington, Ohio, it seemed to me the charges were excessive. For instance, 25 chicks in a little pasteboard box weighing only 3 lbs. was not less than 50 cents *anywhere*, even to the next station. I presume they charge a little more because the chicks must be delivered within three days. Even if this be true, it seems to me the charge is double what it should be, or more than that. Here is something from the *Farmers' Guide* of April 18. It is clipped from a two-column article:

"By a recent opinion and order issued by the Indiana Railroad Commission, express rates in the State are to be reduced on an average of between 10 and 12 per cent. New schedules according to this reduction will be adopted by the express companies within the next thirty days.

"The opinion handed down in this case is one of the most elaborate ever issued by the Indiana Railroad Commission. It is interesting in that it lays bare the history of the express companies from the time that they were first instituted up to the present time. The commission reports that it was with considerable difficulty the investigation was carried on, as very little volunteer information could be secured. Therefore the facts had to be dug up as best they could. Nevertheless, they seem to be quite complete, and will, we think, give the public a new idea of what a universal robbery and public hold-up game the entire express business is."

I should be glad to give the whole article, but a lack of space forbids. In going over this matter in conversation with the Reasoner Brothers, the great nurserymen in tropical plants, Mr. Reasoner commended our editorials in regard to parcels post; and, approaching his desk, he spoke something as follows:

"The whole world knows that the charges of the express companies are out of reason. But that is not all. There is a universal steal going on all over our land in order to get *even more* than these outrageous prices. See here."

He picked up a lot of papers strung on a wire, and resumed: "There has been so much overcharging that I send a printed slip with every shipment, giving the correct amount of expressage, and asking my customers to report at once to me if the agent asked for a larger amount. And here is all this pile of complaints. It would seem that almost every time there is an overcharge, and most people consider it more trouble to readjust and collect than the amount is worth, and so they let it go. Now, this discourages purchasers, clogs our business, and is an outrage on society in general."

I hope the *Guide* and other periodicals will continue to expose and hold up this outrage until we have parcels post in spite of all the express companies with their wealth can do to stop it.

#### THE WRIGHT BROTHERS AND THEIR FLYING-MACHINE

I suppose most of the friends have kept posted in regard to the Wright Brothers, for their exploits have been given in all the papers of the United States. The Wright Brothers themselves have not seen fit to make any report of their doings; but if the report is to be credited, who witnessed their flight (of course at a distance), they have made a record of eight miles in 7½ minutes, which is a little over a mile a minute. They have also a machine that carries two people sitting up as one would in a buggy or an automobile. Lastly they made a trip out over the ocean, two miles and back; but their machine was finally disabled by an accident, obliging them to lie off for a time for necessary repairs; but as they have other machines here in Ohio, however, we shall expect to hear from them further very soon.

Later.—Since the above was dictated we find the following in the *Bangor, Me., Weekly Commercial*:

Thursday's experiments proved but a repetition of Wednesday's achievements, when the dauntless aeronauts accomplished four successful flights, two of them after sunset, covering three and a half to four miles each time, and doing four miles down the coast in two minutes and fifty seconds at an altitude of forty feet. The aeronauts alighted each time, moreover, at the place of starting.

Thursday's flights were satisfactory to the inventors, and both the morning and afternoon were utilized. The inventors were astir early, and had their airship ready and in operation at an hour when it was impossible for the visitors to reach the immediate neighborhood of Kill Devil from Manteo, a place where strangers can be domiciled, a good dozen miles across the sound. Every thing favored the test.

The inventors will continue their experiments there as long as they can do so without being hampered by too many curious eyes. The aeronauts are afraid some one may learn their secret, and they are taking no chances in safeguarding the machine. They keep it in a sheltered house behind a sand dune, near the life-saving station, and they sleep close to it with a loaded rifle within reach. When any person, such as a newspaper correspondent or a photographer appears anywhere on the beach, the inventors lose no time in covering the aeroplane and carrying it to their house. Nevertheless, quite a number of visitors have arrived in the vicinity, mostly magazine and newspaper writers, and photographers.

# ARE YOU LOOKING AHEAD?

Mixed farming as a profitable occupation is no longer an experiment in the Dakotas and Montana. Most of the products of the Middle West are successfully raised there each year without irrigation.

Where a few years ago cattle-raising was the principal occupation, settlers are now successfully engaging in diversified farming, truck farming, dairying, and poultry-raising. To-day's opportunities in these lines are along the Pacific Coast extension of the

## Chicago Milwaukee & St. Paul Railway

Good land may be bought from \$15 an acre upward along this new line in the Dakotas and Montana. Plenty of government homestead land may still be secured close to the towns on this new line. Markets for the crops are assured.

Homeseekers' excursions to points on the new line in the Dakotas and Montana on June 2 and June 16. Low fares; stop-overs allowed. Tickets good 21 days from date of sale. Complete information free.

Books describing the present opportunities along this new line are free for the asking.

## Ridpath's History of the World

9 Massive Royal Octavo Volumes, 4000 double-column pages, 2000 superb illustrations. Brand New, latest edition, down to date, beautifully bound in half Morocco.

**At LESS than even DAMAGED SETS were ever sold**

We will name our price only in **direct letters** to those sending us the **Coupon** below. **Tear off the Coupon, write name and address plainly, and mail to us now before you forget it.**

Dr. Ridpath's family derive an income from his history, and to print our price broadcast, for the sake of more quickly selling these few sets, would cause **great injury to future sales.**

Weights  
55 lbs.

**RIDPATH** takes you back to the dawn of history long before the Pyramids of Egypt were built; down through the romantic, troubled times of Chaldea's grandeur and Assyria's magnificence; of Babylonia's wealth and luxury; of Greek and Roman splendor, of Mohammedan culture and refinement; of French elegance and British power; to the rise of the Western world, including the complete history of the United States and all other nations down to the close of the Russia-Japan war.

**RIDPATH'S** enviable position as an historian is due to his wonderfully beautiful style, a style no other historian has ever equaled. He pictures the great historical events as though they were happening before your eyes; he carries you with him to see the battles of old; to meet kings and queens and warriors; to sit in the Roman Senate; to march against Saladin and his dark-skinned followers; to sail the southern seas with Drake; to circumnavigate the globe with Magellan; to watch that thin line of Greek spearmen work havoc with the Persian hordes on the field of Marathon; to know Napoleon as you know Roosevelt. He combines absorbing interest with supreme reliability, and makes the heroes of history real living men and women, and about them he leaves the rise and fall of empires in such a fascinating style that history becomes as absorbingly interesting as the greatest of fiction.

**RIDPATH'S History** is strongly endorsed by Presidents Harrison, Cleveland, and McKinley, Jefferson Davis, Lew Wallace, John L. Stoddard, Bishop Vincent, Dr. Cuyler, Rabbi Hirsch, Presidents of Ann Arbor, Amherst, Brown, Dartmouth, Tufts, Trinity, Bates, Colby, Smith, Vassar, Yale, and other colleges, and by the great American People, 200,000 of whom own and love it.

**RIDPATH'S History** will be a household treasure. You'll buy it some time, anyhow. It's fast getting into all comfortable, well-to-do American homes. Here's a chance to get it for about half what it will cost if you let this opportunity slip. Isn't it wise to get it now?

**RIDPATH'S** is conceded the **Greatest History** ever written. It is so **beautifully written** your children will learn to **love it**. It is the **only** general history recognized as an **authority**. This is your chance to buy it for **much less than ever before**.

# ITALIAN Queens

and bees, and nothing but Italians. An improved superior strain is what QUIRIN-THE-QUEEN-BREEDER raises. Our stock is northern-bred and hardy. We just visited our outyards (all wintered on summer stands), and not a colony is dead to date (March 18). Some hives have lost scarcely a bee, so it appears. BROTHER BEE-KEEPER, how do you like such stock for hardiness? A party up in Maine got 50 nuclei of us several years ago. We just received a letter from him. He is after more of our bees, because last season he got 2200 pounds of honey which sold for 22 cts. per pound. Our stock is well known throughout the United States. Some of the largest yields reported can be traced to our stock. Over 20 years a breeder. Free circular and testimonials. Price of stock as below.

| Prices of Queens before July.   | 1      | 6      | 12      |
|---------------------------------|--------|--------|---------|
| Select queens . . . . .         | \$1 00 | \$5 00 | \$ 9 00 |

This handsomely illustrated, fifty-page, booklet containing a most interesting description of the famous Manatee section, being a reproduction of a series of articles written by the editor of one of the leading agricultural papers in the United States after a personal investigation by him. The articles were run in serial form in his publication during the last four months, and we have embodied same in an attractive pamphlet, illustrating it with dozens of interesting and instructive scenes from actual life. This handsome piece of literature will be thoroughly enjoyed and worthy of preservation, and will be sent free, together with pamphlet containing a list of properties available in the LAND OF MANATEE upon receipt of five cents in stamps or currency to cover cost of mailing. Our supply of this booklet is limited, and if you want a copy you should not delay, but write at once.

## Honey Markets.

The prices listed below are intended to represent, as nearly as possible, the average market prices at which honey and beeswax are selling at the time of the report in the city mentioned. Unless otherwise stated, this is the price at which sales are being made by commission merchants or by producers direct to the retail merchant. When sales are made by commission merchants, the usual commission (from five to ten per cent), cartage, and freight will be deducted, and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage, and other charges, are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

### EASTERN GRADING-RULES FOR COMB HONEY.

**FANCY.**—All sections well filled, combs straight, firmly attached to all four sides, the combs unsoiled by travel-stain or otherwise; all the cells sealed except an occasional one, the outside surface of the wood well scraped of propolis.

**A No. 1.**—All sections well filled except the row of cells next to the wood; combs straight; one-eighth part of comb surface soiled, or the entire surface slightly soiled; the outside surface of the wood well scraped of propolis.

**No. 1.**—All sections well filled except the row of cells next to the wood; combs comparatively even; one-eighth part of comb surface soiled, or the entire surface slightly soiled.

**No. 2.**—Three-fourths of the total surface must be filled and sealed.

**No. 3.**—Must weigh at least half as much as a full-weight section.

In addition to this the honey is to be classified according to color, using the terms white, amber, and dark; that is, there will be "Fancy White," "No. 1 Dark," etc.

### NEW COMB-HONEY GRADING-RULES ADOPTED BY THE COLORADO STATE BEE-KEEPERS' ASSOCIATION.

**No. 1 WHITE.**—Sections to be well filled and evenly capped except the outside row, next to the wood; honey white or slightly amber, comb and cappings white, and not projecting beyond the wood; wood to be well cleaned; cases of separated honey to average 21 pounds net per case of 24 sections, no section in this grade to weigh less than 13½ ounces.

Cases of half-separated honey to average not less than 22 pounds net per case of 24 sections.

Cases of unseparated honey to average not less than 23 pounds net per case of 24 sections.

**No. 1 LIGHT AMBER.**—Sections to be well filled and evenly capped, except the outside row, next to the wood; honey white or light amber; comb and cappings from white to off color, but not dark; comb not projecting beyond the wood; wood to be well cleaned.

Cases of separated honey to average 21 pounds net per case of 24 sections; no section in this grade to weigh less than 13½ ounces.

Cases of half-separated honey to average not less than 22 pounds net per case of 24 sections.

Cases of unseparated honey to average not less than 23 pounds net per case of 24 sections.

**No. 2.**—This includes all white honey, and amber honey not included in the above grades; sections to be fairly well filled and capped, no more than 25 uncapped cells, exclusive of outside row, permitted in this grade; wood to be well cleaned, no section in this grade to weigh less than 12 ounces.

Cases of separated honey to average not less than 19 pounds net.

Cases of half-separated honey to average not less than 20 lbs. net per case of 24 sections.

Cases of unseparated honey to average not less than 21 lbs. net per case of 24 sections.

**INDIANAPOLIS.**—With the exceptions of a few lots of old comb honey the local market is practically bare of honey. Dealers are awaiting arrival of new crop, but as yet no prices are established. Beeswax brings 28 cents cash or 30 in exchange for merchandise.

WALTER S. POWDER,  
Indianapolis, Ind.

**PHILADELPHIA.**—Very little doing in the honey market for the last two weeks, with the prospect ahead of an unusually big crop in the East. Buyers are holding back for the new crop, old crop of comb being packed away for fall trade. Not enough sales being made of comb honey to make any quotation. Extracted honey, Southern, arriving freely. Bright amber sells in barrels at 6; white honey in 60-lb. cans, in a small way, 8.

W. A. SELSER,  
Philadelphia, Pa.

May 25.

10 Vine St., Philadelphia, Pa.

**NEW YORK.**—Comb honey: The demand is next to nothing, and has been so for the past four months. A few crates of fancy No. 1 white are called for once in a while, while off grades and dark are entirely neglected. As there is practically no demand, quotations are simply nominal. We have more in stock than we can dispose of. The honey will have to be carried over until next fall. We can not encourage shipments of comb honey, as we do not think we shall be in position to render account of sales within reasonable time. Extracted honey: Demand better and market slightly improving. New crop is arriving quite freely from the South, where the yield seems to have been pretty large. We quote California white sage at 8½ to 9; light amber, 7½ to 8; amber, 6 to 6½; new crop Southern from 58 to 75 per gallon, according to quality. West India honey is arriving in fairly good-size lots and finds ready sale at from 60 to 62 per gallon, duty paid. Beeswax in good demand and firm at 30 to 31.

June 4.

HILDRETH & SEGELKEN,  
265-7 Greenwich St., 82-6 Murray St., New York.

**SAN FRANCISCO, CAL.**—The first offerings of the new crop of honey have arrived and have been picked up eagerly by the dealers as soon as they arrived. There has not been a sufficient amount of this to make any marked difference, and the market is still in a very bare condition. The dealers are still anxiously awaiting the arrival of substantial shipments. Prices remain as last stated. Water-white, comb, 16 and 17; white, 15; water-white, extracted, 8 and 8½; light amber, extracted, 7 and 7½; dark amber and candied, 5¼ and 5½. —*Pacific Rural Press.*

June 6.

**DENVER.**—Our market is now entirely cleaned up of comb honey, and the first consignments of the new crop should find a ready sale at good figures. We quote extracted white, 8 to 9; light amber and strained, 6¼ to 7½. We pay 25 cents per pound for clean yellow wax delivered here.

May 26.

THE COLORADO HONEY-PRODUCERS' ASS'N,  
F. RAUCHEFUSS, Mgr., Denver, Colo.

**LIVERPOOL.**—The market for honey and beeswax is steady and quiet. We quote honey, Chilian, 4 to 6½ cents; Peruvian, 3½ to 5½; California, 7½ to 9; Jamaican, 4 to 5½; Haiti, 6½ to 6¾. Beeswax is very firm—African, 30 to 32; American, 30 to 33; West Indian, 29 to 32; Chilian, 30 to 36; Jamaican, 34 to 35.

May 13.

TAYLOR & CO.,  
7 Tithebarn St., Liverpool.

**ST. LOUIS.**—The honey market is very quiet. There is absolutely no demand for comb honey. Extracted honey is also neglected, consequently the prices have declined. Quote as follows: Fancy white comb honey, 15 to 16; No. 1, white and amber, 12 to 14; broken and defective, less. Extracted white, in cans, nominal at 8 to 8½; amber, 7 to 7½; in barrels, 5½ to 6; granulated extracted honey sells at less. Beeswax, 29 for prime; impure and inferior, less. R. HARTMANN PRODUCE CO.,

May 11.

St. Louis, Mo.

**ZANESVILLE.**—So light is the demand for honey at the present time that it is almost useless to quote the market. Stocks are pretty well reduced, and there is a tendency to cut prices, especially on the part of one-horse dealers. While the remnant of last year's crop is moving very slowly, some revival is anticipated with the arrival of the new crop. For good quality beeswax I offer 30 cts. in exchange for bee-supplies. Wax wholesales at 40 to 45.

May 18.

EDMUND W. PEIRCE,  
Zanesville, O.

**BUFFALO.**—There has been no change in the price of honey since last quoted. The demand is fair for pure white comb and good No. 1 buckwheat comb. We think that about all the honey in the market will be cleaned up before the new crop is ready.

May 11.

W. C. TOWNSEND,  
Buffalo, N. Y.

**CINCINNATI.**—The market on extracted honey is light. We quote light amber in barrels at 6½; California white sage, 9½; practically no demand for comb honey. Beeswax sells at 33.

May 23.

C. H. W. WEBER,  
Cincinnati, O.

**KANSAS CITY.**—We have nothing to quote in the way of comb honey; but we quote extracted white at 7½. Beeswax, 25 to 27.

May 9.

C. C. CLEMONS & CO.,  
Kansas City, Mo.

**CHICAGO.**—The honey market is without volume—no special change in price of either comb or extracted. Much of the extracted from Utah will be unsold when this year's crop is harvested unless it is sold to bakers. Beeswax is steady at 30.

May 9.

R. A. BURNETT & CO.,  
Chicago, Ill.

## The Fred W. Muth Co.

THE BUSY BEE-MEN

51 Walnut St.

Cincinnati, Ohio

# GLEANINGS IN BEE CULTURE

Established  
1873.  
Circulation  
32,000.  
72 pages.  
Semi-  
monthly.

Devoted to Bees, Honey, and Home Interests.

Published by THE A. I. ROOT CO., Medina, Ohio.  
J. T. CALVERT, Business Manager.

\$1 per year.  
When paid  
in advance:  
2 years, \$1.50.  
3 years, \$2.00.  
5 years, \$3.00.

POSTAGE IS PREPAID by the publishers for all subscriptions in the United States, Hawaiian Islands, Philippine Islands, Guam, Porto Rico, Tutuila, Samoa, Shanghai, Canal Zone, Cuba, and Mexico. Canadian postage is 30c per year. For all other countries in the Postal Union add 60 cents per year postage.

CHANGE OF ADDRESS. When a change of address is ordered, both the new and the old address must be given. The notice should be sent two weeks before the change is to take effect.

DISCONTINUANCES. The journal is sent until orders are received for its discontinuance. We give notice just before the subscription expires, and further notice if the first is not heeded. Any subscriber whose subscription has expired, wishing his journal discontinued, will please drop us a card at once; otherwise we shall assume that he wishes his journal continued, and will pay for it soon. Any one who does not like this plan may have it stopped after the time paid for it by making his request when ordering.

HOW TO REMIT. Remittances should be sent by Draft on New York, Express-order or Money-order, payable to order of The A. I. Root Company, Medina, Ohio. Currency should be sent by Registered Letter.

AGENTS. Representatives are wanted in every city and town in the country. A liberal commission will be paid to such as engage with us. References required.

## Foreign Subscription Agents.

Foreign subscribers can save time and annoyance by placing their orders for GLEANINGS with any of the following authorized agents, at the prices shown:

PARIS, FRANCE. E. BONDONNEAU, 142 Faubourg St. Denis. *Per year, postpaid, 7½ fr.*

GOODNA, QUEENSLAND. H. L. JONES. Any Australian subscriber can order of Mr. Jones. *Per year, postpaid, 6/.*

DUNEDIN, NEW ZEALAND. ALLIANCE BOX CO., 24 Castle St. *Per year, postpaid, 6/.*

# BOOKS of All Kinds on CREDIT

ON  
YOUR OWN TERMS.  
TELL US YOUR WANTS.

Established 1860 THE FRANKLIN-TURNER CO., Atlanta, Ga.

**TERMS: Name your own TERMS.** For years we have tried to develop a plan whereby the Masses could be enabled to get any books they want and need for Self-Education or pleasure without being forced to pay cash.

**NOW**, if you are worthy, though poor, cut this ad out, mark X by the book or books you are interested in, mail to us at once and we will send you illustrated circulars and prices of the books marked.

After you get our literature and decide to order then tell us how and when you can pay for the books you want. If you are reasonable in **YOUR TERMS**, we will gladly ship your order. And if books are not as represented, you can return them at our expense.

Be sure and mention this paper.

Ohio Hatchery and Mfg. Co., box 40, Bellevue, O.

**CUTS** USED IN THIS MAGAZINE  
ARE FROM  
**THE MUGLER ENGRAVING CO.**  
MUGLER BLDG. CLEVELAND, OHIO.

## A NEW HIVE-TOOL

Hitherto we have said very little about our new hive-tool, but after submitting it to some of the foremost bee-keepers of America for their candid opinion—for or against—the universal verdict is that it is a good thing; though it looks like a very simple tool it is very surprising how useful it is to an apiarist. The bent end, for example, is just right for severing Hoffman frames. A slight twist of the wrist does the business without angering the bees, and one's hand is so placed the bees do not see it. For scraping wax and propolis nothing could be finer, and it is better than a chisel, screwdriver, or putty-knife for opening hives. Any bee-keeper will be glad of one in his pocket ready for all occasions. It is made of the finest hardened steel nickel plated.

### Sample Testimonial:

*Mr. Root:*—I have been using your nickel-steel hive-tool this spring, and am very much pleased with it. It is the best thing I have tried yet. I, with my helper, have been using tack-pullers heretofore; but this is better because so much stronger. It leaves nothing to be desired except that there should be a hole in it a little nearer the crooked end. I tried to get one drilled but had to give it up—too hard; so I fastened a strap around it to fasten to my pants button.

Oberlin, Ohio.

CHALON FOWLS.

Price 50 cents postpaid.

Hive-tool, and Gleanings for a year, \$1.25.

THE A. I. ROOT COMPANY,

MEDINA, OHIO.

### THE RESULT OF TOEPPERWEIN'S WORD CONTEST.

1. Edna L. Crocker, Danforth, Me., 448 words.
2. Name unknown, 435.
3. A. B. Shideler, North Branch, Ia., 434.
4. M. W. Tyler, Sweet Springs, Mo., 425.
5. R. N. and L. S. Gillette, Fostoria, Ia., 421.
6. H. Greenwald, Lumberton, N. J., 418.
7. D. B. Kinnison, David City, Neb., 417.
8. James E. Storkey, Converse City, Neb., 417.
9. Ada F. Pellet, Atlantic, Ia., 416.
10. Isaac F. Tillinghast, Factoryville, Pa., 416.
11. H. C. Kautz, North Water Gap, Pa., 415.
12. H. A. Pinegar, Wellington, Utah, 411.

Over 1000 persons entered the above contest. Owing to the immense amount of work connected with such a contest, and the technical knowledge required, Messrs. Toepperwein engaged an expert to examine all the papers, with the foregoing result. The problem was to create as many words as possible out of the word Toepperwein.

### THE SEABOARD AIR-LINE RAILWAY.

Some of our readers may not have noticed the liberal offer made to them by the management of the Seaboard Air-Line Railway, who will, on request, furnish their *Seaboard Magazine* free of charge. It is very far from being a mere advertisement; on the contrary, it will bear very favorable comparison with many journals for which a fair charge is made. It gives very just and accurate information about the land contiguous to the Seaboard Railway. To many of the readers of GLEANINGS this will prove to be very interesting reading because it discusses truck-growing and fruit-growing as best suited to much of these lands. The climate of the country through which this railway passes is extremely pleasant and agreeable compared with the rigorous weather of the Northern States. In many cases two crops may be grown in a season—not only so, but the prices realized are actually greater than are obtained for northern produce. Being early it takes the "cream" of the northern markets, and the gigantic cotton-mills and other factories furnish splendid markets right at home. Moreover, the cotton-planters and their helpers are very great purchasers of northern produce, so that, as a matter of fact, the South is the greatest outlet for produce this country has. For this reason many northern farmers have moved to the South to their own great advantage. Many are puzzled to know just what section to go to, and the *Seaboard Magazine* was started with the express object of furnishing the desired information.

## BANKING BY MAIL

**4 Per Cent INTEREST**  
Compounded Twice a Year.

Assets of over one-half million and the management of prudent men of solid financial standing give this bank every element of safety.

Send to-day for particulars, explaining how you can open an account safely and conveniently by mail.

Under ordinary circumstances all or any part of your deposits may be withdrawn at will.

| Grand Sweepstakes.                                                                         |      |      |     |     |
| 17 Largest, best, and most attractive exhibition in this department, all things considered | 15   | 12   | 9   | 6   |

#### FARMERS' COLLECTION.

Exhibits to compete for the following premiums must be made by bee-keepers living fifty miles or more from St. Paul, and not eligible to exhibit in the general classes.

|    |                                                                  |      |     |     |     |
|----|------------------------------------------------------------------|------|-----|-----|-----|
| 18 | 12 to 24 pounds white comb honey                                 | \$10 | \$7 | \$5 | \$3 |
| 19 | 12 to 24 pounds amber comb honey                                 | 10   | 7   | 5   | 3   |
| 20 | 12 to 24 pounds white extracted honey                            | 10   | 7   | 5   | 3   |
| 21 | 12 to 24 pounds amber extracted honey                            | 10   | 7   | 5   | 3   |
| 22 | Most original and attractive design in comb honey                | 5    | 3   | 2   |     |
| 23 | Best and most attractive display of wax, not less than 12 pounds | 5    | 3   | 2   |     |

| Lot. | OPEN TO THE WORLD.                                                                  | 1st. | 2d. | 3d. |
|------|-------------------------------------------------------------------------------------|------|-----|-----|
| 24   | Candies made with honey instead of sugar; quantity, quality, and display considered | \$6  | \$4 | \$2 |
| 25   | Best display of cooking with honey used in place of sugar for sweetening            | 5    | 3   | 2   |

#### WORKING BEE EXHIBIT.

|    |                                                                                                                                                                                                                                                                                                                           |    |    |   |
|----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----|----|---|
| 26 | Best hive for comb honey                                                                                                                                                                                                                                                                                                  | 5  | 3  | 2 |
| 27 | Best hive for extracted honey                                                                                                                                                                                                                                                                                             | 5  | 3  | 2 |
| 28 | Best display of apian tools and fixtures                                                                                                                                                                                                                                                                                  | 7  | 5  | 2 |
| 29 | The most attractive exhibit of handling bees made by any bee-keepers' association in suitable tent or wire-netting inclosure; said exhibit to be made daily and as many times daily as is deemed advisable by the superintendent of this department. (Associations competing must bear all the expenses of said exhibit). | 40 | 20 |   |

W. W. CARY & SON, LYONSVILLE, MASS.

We wish to recommend this old established firm to the notice of our readers in the New England States. It is one of the oldest if not the oldest concern in the bee-business, being at one time intimately associated with Mr. Langstroth. Messrs. Cary carry a full line of bee-supplies, and are in a position to ship very promptly—in fact, almost by return mail.

# LISTEN!

## DO YOU HEAR THOSE BEES WORKING?

Soon they will want room or will swarm.

Have you gotten your hives and supplies? If not, send your order at once. If you have The A. I. Root Co.'s catalog you can order from it. We sell their goods at their factory prices. We can fill your orders promptly now. Write for further information and our 40-page catalog.

JOHN NEBEL & SON SUPPLY CO., HIGH HILL, MONTG. CO., MISSOURI.

RAUCHFUSS PATENT  
COMBINED SECTION-PRESS AND  
FOUNDATION-FASTENER.

Used by the largest comb-honey  
producers.

## Successful Co-operation

means to the Bee-keeper:—The buying of the best Bee-supplies obtainable at the closest prices, and marketing of his products to the best advantage. Our association is co-operative, and organized for this purpose. We carry a large stock of high-grade goods such as:

G.B.Lewis Co.'s  
Hives and Sections

Root's  
Smokers and Extractors

Dadant's  
Comb Foundation

Send to-day for our free 48-page Illustrated Catalog.

The Colorado Honey-Producers' Ass'n  
1440-1444 Market Street .. .. Denver, Colorado

# BEE KEEPING

will be a profitable  
industry this season.

Honey is high—short crop last year. The shortage of the honey crop for 1907 in the United States warrants bee-keepers to increase their colonies. About a half crop was produced, and in California, where the cheap honey comes from, only a quarter of the average crop was produced.

## Get Ready Now! for More Honey

Let us send you our catalog. We are manufacturers and sell only our own make of bee-supplies. Minneapolis is the largest lumber-distributing point; the Mississippi river furnishes us power, and our organization and labor conditions are the best for economical production. Send us an estimate of your requirements and let us give you prices. We have a large stock of standard bee-supplies on hand.

Dovetailed Hives, Sections, Section-holders, Separators, Brood-frames, Comb Foundation, Smokers, Extractors, Shipping-cases, etc.  
MINNESOTA BEE SUPPLY COMPANY, 23 Nicollet Island, Minneapolis, Minn.

## TO THE BEE-KEEPERS of CANADA.

WE are pleased to say that we are able to offer, in Canada, goods manufactured by The A. I. Root Co. While we do not offer every thing listed in their catalog, we have selected such articles as we believe will best meet the wants of the Canadian beekeepers.

The heavy duty and freight charges we have to pay make it impossible for us to sell in Canada at Root's prices. We have, however, made prices as low as possible, and in no case do we charge nearly as much extra as the amount of freight and duty we ourselves have to pay on the goods.

We would ask you, when comparing our prices with those of other dealers, to take into consideration the QUALITY. If you do so we feel satisfied that you will place your order with us. The splendid quality of the material sent out by The A. I. Root Co. has given "Root's Goods" a world-wide reputation. Remember, "The best is cheapest."

**E. GRAINGER & COMPANY**  
Deer Park, Toronto, Ontario, Canada

Canadian agents for The A. I. Root Co., Medina, O., U.S.A.

## APICULTORES

De Espana, Portugal y Colonias.

Pidan catalogos de las colmenas, extractores, prendas para cera, ahumadores, zinc perforado, escape de abejas, velos, cuchillos, maquinas para hacer base de panales, y todos otros articulos utiles en apicultura manufacturado por la celeberrima casa de

# \$UCCESS\$

This is the way that most people would spell success—begin with a dollar and end with two; and if that is the kind of success you are looking for, you ought to be reading the

## BEE-KEEPERS' REVIEW.

It is not only thoroughly practical, but is conducted from a dollar-and-cent standpoint. It tells its readers how to keep bees in such a manner as to *make money*; its articles are written by men who have made money in the business, and can tell others how to do it.

While on a visit recently a bee-keeper told me that for a long time he had been reading only one bee-journal, but, finally, he had accepted one of my special offers, subscribing for the *Review* and securing a volume of back numbers, and, as he looked over and read the back numbers, he was fairly

## STRUCK DUMB

at the amount of information that they contained—he did not suppose there could be another bee-journal, aside from the one that he had been reading, that could contain so much information.

## SPECIAL OFFER.

Now, if you are not acquainted with the *Review*, you might be equally surprised at its value, and here is an easy way to learn more about it: Send me ten cents and I'll send you three late but different issues, and the ten cents may apply on any subscription that you may send in later. A special offer will also be sent, showing how you can get the *Review* for this year and next at a very low price.

W. Z. HUTCHINSON, Flint, Mich.

## And Still They Come

The following letter from one of our customers demonstrates in his own words the satisfaction our customers receive. Remember this is only one of the many thousands we receive.

Griggs Bros., Toledo, O.:—I received the hives and supplies to-day, which is the quickest I ever got goods after ordering. They must have come over in the Knaben shoe's airship. They certainly are in fine shape—utterly impossible for any thing to have got lost.

Your shipping-clerk had them packed to perfection.

Respectfully, HUGH RICHARDSON,  
Wood Co., O.

We should be pleased to list you as one of our customers if you are not one already. Bear in mind we handle ROOT'S GOODS exclusively, not the cheap shoddy stuff which others are trying to palm off under the pretense that it's "as good as ROOT'S." Try ROOT'S and you will be convinced. TOLEDO is the place to buy; we save our customers annually thousands of dollars in FREIGHT.

A complete line of Incubators and Poultry Supplies listed in our free catalog. Send for one.

Honey and Beeswax wanted in exchange for supplies.

### Special

200 cases of 60-lb. cans, good as new, at 50 cents per can. Special prices in quantities.

## INDIANAPOLIS=THE PIVOT CITY.

*By the Bee Crank.*

Indianapolis is a mighty good town to live in, and a good town for business.

Because—All passenger and freight depots are within five blocks of the business center.

Because—It is only thirty-five miles from the center of population of the United States.

Because—It has eighteen steam railway lines.

Because—It has twenty-five interurban passenger and freight lines.

Because—It is only seventy miles from the vast coal-fields.

Because—It has factories of world-wide reputation.

Because—It has a population of two hundred and forty thousand, and is growing.

Because—It has miles of wide well-paved streets, many well-distributed parks, and thousands of homes surrounded with beautiful lawns and shade-trees.

Because—It has one hundred and seventy-five churches, sixty-five common schools, two high schools, one national technical institute, and one college.

Because—It is the home of the very best bee-supply house in the country, and the only one that makes a distinct specialty of immediate shipments, perfect packing and crating and services, that have been pronounced by scores of bee-men as being absolutely ideal.

I handle Root's goods at their prices—Danzonbaker and other standard hives; finest sections; fresh new comb foundation; smokers and all other first-class equipment for bee-men. My catalog is free.

Beeswax wanted at highest market prices.

Wanted. — Fancy white-clover comb honey for exhibition purposes.

Hoosier-Italian queens ready by return mail. Untested, 75 cents. Select untested, \$1.00.

## STRAY STRAWS

DR. C. C. MILLER

HAVE READ Leslie Burr's article, p. 699. Am going to stay at Marengo. [Most bee-keepers had better stay where they are unless they desire to go into the business of honey production on a very large scale, running a series of yards.—Ed.]

I THOUGHT I did a pretty good thing when I said "cellar the bees" instead of "put the bees in the cellar." Now comes a Canuck, R. B. Ross, Jr., with the word "uncellar." Why not? Ever so much shorter than to say "take out of the cellar."

SORRY you've gone lame in one eye, Mr. Editor, but glad you are going to spend more time with the bees. Better for your readers, and you will live longer. [The eye is apparently holding its own. We feared at one time that it might get worse, and possibly involve the other eye.—Ed.]

W. Z. HUTCHINSON, p. 639, speaks of storing supers of honey in the bee-cellar. Does he really mean *cellar*? That might do in Colorado, just possibly in Michigan; but to store honey in any thing called a cellar in this locality, unless the cellar is heated, comes pretty near spelling ruin. [Here too.—Ed.]

A CARNIO-ITALIAN queen was received from Medina, July 30, 1906—too late for her progeny to do much storing that year. Last year the colony built up well, showed no great inclination to swarm, and stored more than the average. This year it has built up well again. Looks like good stock, judged by this one specimen.

SOMETIMES the objection is made to comb honey that the wax is indigestible. Probably in no case does that do any harm; and in some cases the indigestibility of the wax is its greatest recommendation. In cases of chronic constipation comb honey has been reported beneficial when extracted honey would have no effect.

WONDER what made the difference between Albert I. Mills' experience, p. 701, and that of Mr. Whitney and mine. Could it be that letting most of the bees go down through the escape, as Mr. Mills did, should make the difference? It seems strange that he found a loss with only two supers, and that with thousands of supers I have as yet observed no loss.

A. I. ROOT, let me tell you a little story. Once there was a saloon-ridden town where four boys lived whose fathers were drunkards, and spent all their money at the saloons. You will see a picture of them in GLEANINGS on the right side of p.

698. On the left side you will see the same boys a few months later after saloons were voted out, and the fathers supported their boys instead of saloons.

I DON'T KNOW whether bees that cap the combs watery are always hustlers; but I think I never had any very poor storers that capped watery. But as I work for comb honey I don't believe such bees bring up the quantity stored as much as they bring down the price per pound. It's all right for such bees to find an asylum with Mr. Whitney, page 702, for I suspect he sets them to work on extracting-combs. For extracted honey they are all right.

BERTHA M. TIMONEY, you say your bees are not as neighborly as those bees in Germany, page 703, but perhaps they would be if placed the same as the bees are placed in Germany. Germans do not scatter them all over the ground as we do, but put them very close together. My hives stand in pairs, a space of only an inch or so between each two hives. In a hot time sometimes that space is filled up with bees, and the bees of the two colonies hang out as one cluster. If one hive should be crowded with honey, and the other have lots of room, it would be nothing strange if they should go into partnership and store where there was the most room.

BEE-KEEPERS, I think, generally understand that it is economy to use foundation as thin as possible. In spite of that, thin super has the preference over extra thin more than two to one. Please get bee-keepers to tell why. I gave up extra thin because the bees maltreated it so whenever not actually storing in it. [Yes, we should be glad to have producers report what weight of foundation they use for sections, and why, particularly the *why*. In order that we may hear from as many as possible we should like to get postal-card reports from several hundred. This will be interesting and valuable, especially to those whose minds are not quite made up which to use.—Ed.]

WORKING with bees at night seems to do well with some; but somehow it doesn't seem to fit this locality. Bees crawling all over, like as not to sting where it will hurt—excuse me. [Night-working is not nearly so bad as it may seem on first trial, providing one uses a good lantern, bicycle pants-guards to keep the bottom of the trousers tight, and sleeves protected in a similar manner. Yes, the bees will crawl; but if one goes at the matter properly he will experience but little difficulty. But we would advise night-working only in the case of business men or clerks who do not get home till after daylight hours; and in all other cases where robbing has been very bad.—Ed.]

PROF. COOK has earnestly protested against calling the larva of the wax-moth a worm, and Burton N. Gates repeats the protest in the *American Bee-keeper*, p. 112. Whatever the entomologists may say, the dictionary supports the use of the word "worm;" and so long as we are asked to use in place of the one word five or six words—"the larva of the bee-moth"—we are likely to follow the dictionary rather than the entomologists. Still, I have much respect for my good friends' feelings, and also for exactness of language. I have asked Prof. Cook to give us something short and yet correct to take the place of "worm." As yet he has not done so. In default of something better I venture to suggest "wax-larva." Even then it will be hard to give up the word "wormy." Instead of saying "That comb is infested with the larvæ of the wax-moth" it is ever so much easier to say "That comb is wormy."

REFERRING to footnote, p. 621, I hardly think the position of the dead queen on the excluder is any proof of a combat between queens. A queen or drone killed above an excluder will always be found on the excluder because the bees can not drag them through. You've got to "show me" before I'll believe that one queen can get a grip on another queen so as to sting her through an excluder. [We will admit that dead drones, and occasionally a dead queen, will be found on the perforated zinc, the same being brought there by the bees in the effort to get them out of the hive. But there have been reports where mortal combats have taken place between two queens through the perforations of perforated zinc. The queen that happens to get the right hold on her antagonist will deliver the sting through the perforations. If some of those who reported these occurrences will hold up their hands we shall be glad to have them do so.—ED.]

THE QUESTION as to the proportion of thin to extra-thin surplus foundation having been raised, I asked Dadant & Sons what was the proportion in their sales, and received the following very full reply:

Our sales of foundation last year averaged as follows:  
 Medium brood—42 per cent. Thin brood—11 per cent.  
 Thin surplus—34 per cent. Extra thin—13 per cent.

From this it will be seen that the thin surplus was 2.6 times as much as the extra thin. The medium brood was 3.8 times as much as the thin brood; the total brood, 13 per cent more than the total surplus. Perhaps you might tell us how these figures compare with figures at Medina. [We do not keep an extended record of every grade sold during the year; but we have asked the foreman of our department to give a report of it for the last month, and the figures are as follows: For more ready comparison we put the Dadant figures alongside of ours.

|               |               |
|---------------|---------------|
| Root Co.      | Dadant.       |
| Medium—34     | Medium—42     |
| Light—20      | Light—11      |
| Thin—30       | Thin—34       |
| Extra thin—16 | Extra thin—13 |

The difference in percentage here shown may be due to the fact that we advise extra thin for sections, not because the bees take to it better, for they do not, but because we believe it makes a finer grade of comb honey.—ED.]

OSWALD MUCK gives a full report of the eight golden queens received at the Vienna station

from America, *Bienen Vater*, 323. He concludes by saying that the American goldens are great beauties, but can by no means compete with the natives. I don't question this verdict, but I do question one objection made against them. He says they are great wanderers, some of the golden workers being found in every hive in the apiary. How is it known that the natives were not scattered in the same way? If a few native colonies were in an apiary of goldens, would not scattered native workers be found in all the golden colonies? [Quite right you are. A few goldens among the blacks would be very conspicuous. The fact is, we suspect, from a lot of observation on the point, that all races of bees wander to a greater or less extent, especially in the case of colonies having entrances similarly situated, and with similar surroundings. The young bees in their first flight are not always unerring in returning to the same spot. When they miss it they go back to one very much like it, pointing in the same direction, or having the same external surroundings.—ED.]

## EDITORIAL

THE early bird catches the worm; or, in other words, the first new comb honey on the market secures the best price. The trade is waiting for it, and the bee-keeper who lands his crop first will make a quick sale.

THERE have been abundant rains in our locality, and it is indeed surprising how fast weeds shoot up, thus obstructing the entrances of the hives right where we had used a sickle and cut every thing down nice and clean three or four days before. In the early part of June, when the ground is soaked with water, it does not take long to hinder greatly the flight of the bees at the entrance.

THE last year's honey crop of California having all been disposed of, the returns show that the actual production was about 275 carloads. This year's crop is beginning to appear, but no one seems to be able to make even an approximate estimate of what the amount in carloads will be, as there is a total failure in places and a fair crop in others.

W. K. M.

MR. J. E. CRANE wisely calls attention to the fact that honey is all the better for a little milk with it when served by itself. Cream is even better, to our taste, and such a combination simply slides down. There is no better food under the sun, and both ought to be within the reach of most people. There are very good reasons for supposing that such food will keep consumptive germs at bay, and promote long life and the happiness of health.

W. K. M.

WE take great pleasure in printing elsewhere in this issue the premium list for bees and honey at the Minnesota State Fair. It is a model, and ought to be emulated by every State in the Union.

The superintendent is Mr. M. V. Facey, one of the best-informed bee-keepers in this country. It ought to be noted that the Minnesota authorities are broad and liberal minded, for they have thrown open the competition to the entire world. They surely deserve a splendid response to their generous invitation. The bee-keepers' exhibits ought to be one of the features of the fair.

W. K. M.

#### COMB HONEY LEFT OVER FROM LAST SEASON, AND WHY.

THERE would not have been a pound of comb honey left on the market if producers had made an effort to sell it before the holidays. A lot of it is held over and is now begging a customer. It will be sold as the season opens up again, but at a very low price. Comb honey more than a year old is usually a poor seller.

#### PARCELS POST.

SENATOR CARTER has succeeded in having the bill creating a parcels-post service set down as a special order for December 14th, next. This insures having the whole question come to a vote, when we all shall see who is for and who against. It was evident there would be no opportunity for a discussion this session, so Senator Carter asked for a special order with the before-mentioned result.

W. K. M.

#### WHAT ARE PRICES GOING TO BE FOR THE CURRENT YEAR?

THIS is a hard question to answer. Early indications showed prospects of a good crop of honey in Texas and California; but the realities are reported to have fallen short of the expectation. The clover district promises a big crop. The conditions are certainly ideal for a fine flow, and if there should be a heavy crop of white clover and basswood in the rain-belt it may make prices in the East ease up somewhat, especially if general hard times hang on.

#### KEEPING THE CAUCASIANS UNDER CONTROL.

WE are having quite a time in keeping our Caucasians under control at our south yard. They raise drones as fast as we can trap them and destroy them, even when they have nothing but worker comb. We fear the consequences of letting them get the start of us, if it should develop later that they are not desirable. What do we think of them at this time? We don't know. They are good honey-gatherers apparently, but are great opropolizers and not as gentle as they might be. The first importations seemed to be much quieter than the later ones.

#### MUST BE PURE BEESWAX.

A committee of the Brooklyn Retail Grocers' Association, headed by President Lohmann, held a conference last week with the New York State Board of Pharmacy with reference to their beeswax prosecutions of grocers. It was brought out that the Board was desirous of stopping the sale of "ironing wax" as pure beeswax, whenever the ironing wax is merely a compound. The gro-

cers' representatives made it clear that the trade at large is innocent of any intent to deceive the public in the matter, and it was pointed out that the grocers' associations were ready to co-operate for the purpose of securing honest methods of distributing groceries of all kinds.—*American Grocer*.

#### WILL THERE BE ANY SAGE HONEY FROM SOUTHERN CALIFORNIA?

THE reports we have received from some of our leading bee-keepers, especially in the vicinity of Los Angeles, have been discouraging. The following clipping sent us by a subscriber seems to tell another story:

##### HONEY CROP TO BE A BUMPER.

The honey crop of this season in this county promises to be a bumper. Estimates that have been made up show that the total will be not less than 50 cars, and the figures may run considerably above that figure.

In fact, the bee-men report that it has been one of the best seasons for honey-gathering that the valley has had for several years past. It has been neither too hot nor too cold for the bees to do their best work, and there has been an abundance of bloom for the honey-gatherers to work upon all the latter part of the winter and spring.

The same story comes from all of Southern California. Riverside Co. is also expected to produce 50 cars, and San Diego Co. will do as well. Other Southern California counties have good crops, so that the total for the seven southern counties will foot up 300 cars or more, it is believed. The average crop is considerably below that figure.

All together it has been a very prosperous year for the Southern California bee-men.

In view of the reports we have received from bee-keepers direct, we are inclined to discredit this somewhat. We are inserting it, however; and if those who are in position to know any thing about the real state of affairs in Southern California will please write us at once we shall appreciate it.

#### DIFFERENCE IN TEMPERAMENT BETWEEN COLONIES.

WHAT a difference there is in bees in regard to temperament! Some colonies must be handled with the utmost care, while others, without regard to race even, will stand almost any kind of rough treatment. The other day we struck one colony that came near making us beat an inglorious retreat; but we stood our ground, using plenty of smoke. The sun had gone down, and the atmosphere was dropping slightly. While bees generally are more vindictive under such circumstances, this particular colony was exasperatingly so.

The very next hive we opened, the bees were as quiet as kittens. We kicked and bumped it, but it was still quiet. We ripped out the combs and replaced them with a bang, and still the bees were quiet. The funny thing about it was that the queens of both colonies were reared from the same blood. They were both well-marked Italians. We surmised from the tendency to run to four bands that the queen of the cross colony had been mated to one of those golden drones that have been the cause of some of our peppery bees,\* while the other queen was undoubtedly mated to an ordinary leather-colored drone of imported extraction. The cross queen we shall sell as a hybrid if we sell her at all. We are wondering if it wouldn't be a sin even to *give* her away.

\* We aim to keep our black and cross bees at one yard; namely, the south yard.

# GETTING THE BEES BACK INTO THE HIVE AFTER LIVE-BEE DEMONSTRATION.

A CORRESPONDENT, in referring to the live-bee demonstrations that we have been giving at fairs and elsewhere, wishes to know whether the bees return to the hive readily, or do they cling to the cage after being shaken off the combs? Soon after they have been dumped into the tin pan many of them fly up and cling to the sides of the cage. While these can be scooped off by the handful, many stray bees will cling to the sides of the cage. If it can be left to stand over night, and the cover of the hive from which the bees were taken be put on catcornered, most of the bees will work their way back into the hive. It seems almost impossible to brush them off the wire cloth; and the more one brushes, the more they cling until they become vicious. We have brushed down what we could, and then picked up the rest one by one. Or if we can not wait, smash them and then collapse the cage, putting it into its case.

# HELPING THE NATIONAL BEE-KEEPERS' ASSOCIATION TO ADVERTISE HONEY.

IT will be remembered that, some time ago, the National Bee-keepers' Association received the funds that belonged to the Honey-Producers' League that was organized for the purpose of advertising honey and creating a market for it. A good many at the time thought it was unnecessary to have two organizations. To make a long story short, the League finally voted to disband and to put the funds (nearly \$1500.00) into the treasury of the National, but on condition that such money should be used to spread information concerning honey as a food—in short, to create a better market for it. The National subsequently voted to accept the funds on the conditions named.

A short time ago, through its manager, Mr. N. E. France, it offered prizes for articles on the subject of honey as a food, and why it should be eaten. Out of over thirty sent in, ten were selected for publication. The National is now sending out a large blanket sheet containing all these honey articles. It is requested that the bee-keeper who receives them shall take them to his local papers and get one or more of them published as a matter of news. It is suggested that one article follow the other, thus keeping up a rapid gun-fire on honeys—nothing like *continuous* advertising.

If all the members will take hold of this properly, a great deal of valuable matter calculated to help the honey business, and in particular the local bee-keeper, will be spread broadcast, for these articles are carefully and conservatively written.

Mr. France announces that he has had several thousand copies printed, which members and others may obtain at the rate of \$1.50 per 100; \$2.00 for 250; \$3.00 for 500. Many bee-keepers would do well to buy a supply and scatter them among their customers, especially grocers and others who buy their honey.

We wish to offer a suggestion to the League committee having this in charge—that it endeavor to get one or more of these articles into "boiler-plate"—that is to say, get the firms that furnish plate matter for small local country papers to accept one or more of these articles and put them

into boiler-plate for distribution all over the country. It is well worth trying for.

We may say that they are an exceptional lot of newsy and instructive articles prepared for popular reading, and it is highly important that they receive as wide a circulation as possible. So let every one, whether a member of the National or not, help along in the good work.

# DIAGNOSING COLONIES BY THE BEE-FLIGHT AT THE ENTRANCE.

IN our last issue, page 683, we spoke about giving room to colonies that show unusual activity at the entrance during a heavy flow of honey from fruit-blossoms. Since the flow began from white clover we have been giving room to all colonies at the south yard that showed strong flight, whether the colony where such activity was shown, needed room or not.

The flow has come on very strong. While it is customary to give supers only to strong colonies which, on examination of their combs, show the need of it, in this case we considered it wiser to give room according to the showing at the entrance, irrespective of the actual condition in the hive, providing, of course, it has a good queen and a large force of bees. Why do we take an external diagnosis rather than internal? Let us suppose a couple of cases which are real:

Here is a colony that has a moderate amount of brood in the hive, and a large amount of honey left over; but the bees, although a good force of them, are not flying much—but *why*, we do not know.

Here is another one that has a large amount of brood, with but very little honey in the hive; but the bees are tumbling down at the entrance. The honey-flow has just begun. It has used up all of its available stores in brood-rearing, and has been running "close to shore." The unusual activity at the entrance shows that these bees will probably need room long before the other whose hive is filled with stores and brood, but whose bees are doing nothing.

But there is another point about this external diagnosis that should be considered. When the flow is actually on, colonies needing room first should have first attention, after which the laggards may be given supers or combs. On the other hand, the hive that is sending a lot of bees out to the field should never at any moment be cramped for room in which to store the nectar; for if it starts to building cells, and the bee-keeper is careless enough to allow it to think of swarming, it may be almost impossible to break up the mania; so it is best to keep clear ahead of such bees.

But there is still another point. Entrance diagnosis can be detected by *one quick glance*. The hard workers and early fielders usually receive on top of the cover a stone or stick, or some mark to indicate which hive needs room first. After all the hives in the apiary that show that they will need room soon are so marked we give them supers or combs.

# DIAGNOSING SAMPLES OF DISEASED BROOD.

DURING the summer, nearly every mail brings us several samples of dead brood to examine. In many instances there are no symptoms of disease

present, showing that the brood was very likely either starved, chilled, or possibly poisoned. We can not always be sure, judging simply from a single piece of brood-comb, and it is quite important that we receive by the *same mail* a description of the trouble as well. We should know the number of colonies affected, whether it was ever noticed before, whether there are other diseased colonies in apiaries near by, etc.

In sending the sample, select as characteristic a piece as possible, four or five inches square. Wrap it in paraffined paper and pack it securely in a wooden or tin box. (Do not use a cigar-box, as the odor of the tobacco almost entirely conceals any possible odor of the brood.) *Be sure to have your own name and address written plainly on the outside of the box;* for when there are several samples received at once there is no way of identifying them unless the name is given.

#### CUTTING ALFALFA BEFORE IT IS RIPE; THE ACTION OF THE IDAHO BEE-KEEPERS.

THE Idaho bee-keepers have hit on a very excellent way of helping the bee industry. They propose to inaugurate a campaign of education to induce alfalfa farmers to let their crop stand until it is in full bloom before cutting. It is quite probable they will be successful, as they have both science and practical experience in their favor. It is not a difficult matter to show that cutting alfalfa before it is ripe is poor business. By letting the crop stand for a few days longer they will get 20 to 25 per cent more of cured hay, and at the same time secure fully as good a fodder.

It is very true the early-cut alfalfa hay has a larger percentage of protein than the late-cut; but the latter contains quite enough protein to suit the most exacting feeder of farm animals. The early-cut alfalfa, on the other hand, is deficient in carbo-hydrates—very essential constituents of all foods, either for animals or men. As a matter of fact, the carbo-hydrates and protein in normal alfalfa hay are so perfectly balanced that there exists no special need of increasing the proportion of either.

It has been shown that we can make further improvement in the culture of alfalfa by allowing it to grow to its maximum before cutting; and then, when it is still in the cock, "sweating" it by covering with a piece of cotton cloth to protect the process of fermentation from the sun. In this manner the very highest grade of hay is produced.

The Idaho bee-keepers may also try to get the alfalfa farmers to mix a reasonable quantity of sweet clover with their crop. Even so great an authority as Joseph E. Wing recommends this course, as the animals like such a mixture, and it is probable the crop is actually increased thereby. The United States Department of Agriculture could do yeomen service along the lines here indicated.

There is one excellent rule for mowing alfalfa so as to get it to grow vigorously immediately after it is cut. It is this: Wait until the buds have started at the base of the stem before cutting. If this rule is observed the plants start to grow almost immediately after mowing. If the cutting of alfalfa is delayed too long after the appearance of the buds, the hay will be woody

and unsatisfactory. If cut too soon, alfalfa will be checked in its growth, and it will be long in yielding a second crop. W. K. M.

#### A WORD OF CAUTION FOR THOSE WHO HAVE HONEY FOR SALE.

BEE-KEEPERS will soon be marketing their honey. At this time it seems proper to reiterate our annual caution to be careful *where* one ships. If the honey is sold outright he should be sure that the party to whom it is consigned is responsible. Let him go to his bank and have it look him up. If he can get no information he should require cash in advance or ship by freight C. O. D.—that is, send a bill of lading to some bank where the customer is located, requesting it to collect the cash before the goods are turned over.

Some argue that, if a house is not responsible, it is safe to send the honey on commission because the consignee can be arrested and jailed if he does not make returns; but if he is dishonest there is nothing to prevent him from making very meager returns, leaving the burden of proof on the producer to show that they are not entirely adequate for the quality of the goods. To do this requires the aid of an attorney and due process of law; and on small shipments the commission man knows it will cost more than the amount involved.

As a rule, bee-keepers should deal with only reliable commission men—particularly those who furnish regular quotations for the bee journals; and in every case where possible one should sell outright. If the goods are fancy or No. 1, and the house is reliable, a cash sale can usually be effected, for the business is getting to be done more and more on a cash basis.

In case one has a lot of off-grade honey—dark or otherwise inferior goods—it may be necessary to sell on commission. Such lots are usually disposed of in that way, for no house will buy outright a shipment of that kind when it does not know what it is, much less how much it will bring in the market.

As we said before in these columns, all dark or inferior-flavored honey should be taken out with the extractor. Nothing but the very best *table* honey should be marketed in sections, and even then all No. 2 should be sold around home.

It is well for the novice to understand that old producers who deal *on the square*—that is, sell their honey for *just what it is*—and offer only first-class goods, have no difficulty in making cash sales and at good prices—usually above the market. The dealer has come to *know* them for their square dealing, and he has no hesitation in entering into a cash deal, and not infrequently wires his acceptance of the quotation. In the case of some producers the honey is sold before it is actually off the hives.

#### THE HONEY SEASON AND PROSPECTS.

REPORTS from most localities in the clover belt continue to be very favorable. As a sample of what is coming in we make a few quotations:

Illinois.—"Bees in this section are gathering honey by the barrel from white clover."

Indiana.—"We have a big crop of white clover, and I think there is a fine honey prospect."

Kentucky.—"Bees are booming just now, with fine prospects for white honey."

Kansas.—"Never were bees in such fine condition; prospects are favorable."

Minnesota.—"Bees light but strong. White clover opens up well."

Kansas.—"I never saw bees in such fine order. If we have a dry year we shall have a good honey crop."

Iowa.—"Bees are in fine condition here. I have had several swarms."

California.—"Bees are doing well at Ioamosa, working on orange-bloom, and beginning on sage." Elsewhere in Southern California the reports are not favorable.

In the northern part of the State the situation is better. The following from the *Pacific Rural Press* will explain:

The *Chico Enterprise* says: "Orange honey, which is pure white, only slightly inferior to sage, will be a full crop; perhaps the largest in the history of the industry. The orange-groves probably will produce 25 carloads. Except for the fact that it crystallizes quicker, orange honey is equal to sage. The other honey-producing sections have been badly affected by drouth. In about 25 per cent of the hives the production will be very small. The other half will produce fairly well, but not a full crop. Last year the State produced 275 carloads. The holdings of honey are not large, but apparently many holders are not aware of the situation, and are still selling at below the actual value based on the prospective short crop. Whatever honey is carried over will be good property, as it does not deteriorate materially in a year. It crystallizes, but when melted it comes out all right and will remain in a liquid state for another year."

Wisconsin.—"Prospects are exceedingly good—never saw so much white clover."

West Virginia.—"We are having the best honey season we have had in ten years, and more swarms than were ever known before."

Pennsylvania.—"Prospects are that this will be one of the best seasons we have ever had."

Georgia.—"Bees have been doing well."

Florida.—"Some report good crops, and some report almost a failure."

In a general way we may say there have been heavy rains and hot weather. In most of the Northern States clover has come out remarkably well; and at this writing the flow is just beginning. But "there's many a slip 'twixt the cup and the lip," and therefore we are looking to see what old Dame Nature will do.

#### THE FOLLY OF ORDERING BEE-SUPPLIES TOO LATE.

THE following letter from a prominent dealer in bee-keepers' supplies in New York carries its own moral:

*The A. I. Root Co.*—Orders are now pouring in. Why don't bee-keepers order goods before they need them? Nearly three hundred dollars' worth of orders came in to-day.  
Syracuse, N. Y., May 25, 1906. F. A. SALISBURY.

In Mr. Salisbury's case we are informed that he has a large stock of goods on hand; but in most cases the dealer is swamped this season with orders because he can not get goods fast enough from the factory. The trouble is, the dealer did not lay in a large enough supply in the fall, taking advantage of the discount, and then when he calls on the factory he is unable to get the goods promptly. What is true of the dealer is more true of the consumer.

Bee-supplies should be bought and put together in the fall and winter months. It is folly to wait until the last minute, when the honey-flow is nearly on, before ordering the goods. Yet experience shows that is precisely what many are doing. They wait till they know there is to be a flow and then order. The honey comes with a

rush, but the goods do not. Result, they have bought and paid for something they can't use; the honey comes, swarms come out galore; kegs and barrels are pressed into service. The honey in such contraptions is not marketable, and then the dealer comes in for a scoring.

#### THE DIFFICULTY OF FINDING QUEENS IN A POPULOUS COLONY; WHEN TO CLIP; SEE FRONT COVER PAGE.

ON the front cover page of this issue we present a view taken in our home apiary, situated just back of one of the factory buildings, showing Mr. C. F. Bender, of Plano, Ill. (who was then in our employ), at work hunting for a queen in a populous colony. The scene is fairly representative of almost any section of our home yard.

We do not often have as populous colonies as this for queen-rearing; but the presence of the Boardman feeder at the entrance indicates that the colony in question is devoted to cell-building, for all such colonies, unless honey be coming freely from natural sources, must be given liberal stimulative feeding. Mr. Bender has removed the cell-building frame, and, as we remember, was hunting for a young virgin that emerged from the cell prematurely. Frame after frame had to be removed, and, as fast as examined, set down on end as shown. Sometimes the task of locating a virgin is a difficult one, as she may go off on a mating-flight; and even if she be in the hive she is but little larger than an ordinary worker bee, and her erratic dodging results often in a fruitless search.

That is one reason why queen-breeders have virgins mated from comparatively weak colonies or nuclei. The weaker they can be and still maintain their collective individuality without replenishing with fresh bees, the better.

But the picture shows another thing—namely, that if one practices clipping queens he should go through his hives as early in the spring as practicable, when the colony has a light force of bees, and when the queen can be easily located. To defer the operation until near swarming-time means going over the combs thickly covered with bees, not once, but sometimes two or three times, and not infrequently the searcher may have to close up the hive for the time being, and then come back an hour or two afterward and hunt again. Occasionally we have seen a colony like the one shown on the front cover, where the owner was almost in despair because he could not find the queen. He sees the eggs and brood in all stages. He *knows* she "is there; but where, oh! where is she?"

Where a colony is very populous, or is on the eve of a honey-flow, or right in it, the queen-hunt should be conducted during the middle hours of the day when a large percentage of the flying bees are in the air. If many are in the field, all combs removed should be stationed in the rear of the hive rather than the front. In this case we requested Mr. Bender to put them in front, where the camera could catch them.

In speaking of Mr. Bender we may say that we consider him one of the best bee-keepers and one of the closest observers in the country. He left our employ of his own accord; and in spite

of the fact that we offered him an advance in salary he said this was no object, as there were other considerations that required his presence at home.

#### BEEES IN SOUTH AFRICA.

**BEE-KEEPING** in South Africa is making progress. One of the drawbacks is the high price of the necessary bee-appliances, due to high freight rates by sea and land, and a high tariff besides. Certain birds and animals prey on bees; but by far the worst is a kind of wasp which seizes the flying bees. The colonists capture these nuisances by means of sticks or twigs coated with birdlime placed near the apiary. The wasps settle on these stakes for the purpose of watching their opportunity to catch bees but are held by the sticky stuff. One small twig will catch a good many. How would this work on the bee-hawks which infest some parts of Florida? They have the same habit of poisoning themselves on the end of a twig to watch their prey. The birdlime is made by boiling linseed oil for hours till it becomes quite sticky. It may also be made from the inner bark of the holly, the juice of the oleander, or the sap of the bread-fruit and similar trees. The following very interesting letter on the subject recently appeared in the *Agricultural Journal of the Cape of Good Hope*: W. K. M.

Locally this pest is called "bijvanger," or "bee-pirate." In Bechuanaland it very much resembles the common English wasp. If this is the same insect as is referred to by Mr. F. Lindenberg, I must beg to differ as to its method and reason for capturing bees. The bee-pirate catches the bee returning to the hive, for the purpose of robbing it of its honey. It first makes its appearance in spring, about the time of the first honey-flow, generally about 8 A.M., when the sun is getting hot, knocking off about 5 P.M., when the day is cooling. It sits near the entrance of the hive, and catches the bees returning heavily laden with honey, either falling with the bee close to the hive, or beating it off some score of yards. It disables the bee, but seldom kills it outright—at least, those that I have managed to find after the pirate leaves them crawl along the ground, unable to fly, generally being quickly despatched by ants. Bees laden with pollen are never touched. Though in hot weather at midday the bees will half cover the flight-board, they are not molested by the pirates, though the latter will also settle on the flight-board. This, I think, proves that it is not the bees alone that they are after. I know nothing that will do away with them. Quantities can be killed by striking them with sticks, and by setting birdlime on points of vantage. I have also tried placing the hives behind a big bush, so that the bees might have some chance among the twigs, but it was of no use. They know by instinct that the pirates are there, and will not work. We consequently have poor takes in this country, 30 sections being a good average. Not so in the Eastern Province, where I had no trouble in averaging over 90 sections for 20 hives. There are no bee-pirates there, and bee-forage is abundant.

Section honey is most in demand. People will not take to Colonial extracted honey. They want proof of its purity by seeing the comb. I do not think it is of much use for the government to provide experts to encourage bee-keeping unless they first place a prohibitive tax on imported honey, reduce that on appliances, etc., and reduce railway rates. Even now honey fetches no better price near the coast than in England, and hives and bee-goods are 50 per cent dearer. In such a thinly populated country the demand for honey is not so great as it would appear, and too many bee-keepers would cause a glut in the market, and bee-keeping would cease to pay. Many Dutch and most Kafirs prefer "young brood" to honey, both as a food and for making drinks and yeast. These will never be induced to produce honey.

I can not understand importing bees to this country, with the risks of foul brood, which, if it once obtains a footing, will never be eradicated. Our duty is rather to export bees. I believe our bees are equal to those of any country, and why not better? They are well marked and colored, most wonderful workers of excellent comb honey, easily handled with ordinary care, and more easily subdued than the English bee—provided they have honey to fill themselves on being alarmed.

I have had no trouble in taking wild nests and securing the bees. After driving the bees I tie a piece of comb containing young larvæ in the hive prepared for the swarm. I then throw a few bees on the top of the frames and close down. I then, if possible, secure the queen and place her in the hive, and throw

the remainder in front of the hive, when they will soon run in. In a few hours the bees will be seen working. They will never leave, provided honey is obtainable; if not they may "hunger swarm," which is prevented by placing an excluder over the entrance and by feeding. This is advisable in any case, as in this country we have the death's-head moth, which enters the hive after honey, and a large black beetle which devours the young larvæ. A space should, however, be left for the exit of the queen at swarming or mating time, and for the easier removal of dead bees.

Vryburg, South Africa.

W. H. EDMUNDS.

#### THE STAND OF THE ONTARIO DEPARTMENT OF AGRICULTURE ON THE SUBJECT OF SPRAYING FRUIT-TREES WHILE IN BLOOM.

ON this question we have just received from Prof. P. W. Hodgetts, of the Ontario Department of Agriculture, Canada, something that will be of special interest to bee-keepers and fruit-growers alike. Prof. Hodgetts represents both departments of the fruit-growing and honey-producing business, and his statement gives tremendous weight to the contention of bee-keepers and the intelligent and progressive fruit-growers of this country, that the spraying of trees while in bloom is attended with loss by both interests. His letter is as follows:

#### ONTARIO DEPARTMENT OF AGRICULTURE.

PARLIAMENT BUILDINGS, TORONTO.

Fruit and Honey Branch,

P. W. HODGETTS.

TORONTO, May 28, 1908.

*Dear Sir*—I note in one of your late issues a reference to the spraying of fruit-trees in bloom, and the consequent loss of bees therefrom. This subject was thoroughly debated in full by our fruit-growers' and bee-keepers' associations a number of years ago, and an act was passed prohibiting the spraying of fruit-trees while in bloom. The act has been enforced in a number of cases, and for a few years a reward was offered by the Provincial Association for the detecting of such cases. For the past few years, however, we have done away with the reward, as it was not found to be necessary. We have been distributing placards among the members of the Association, and have asked them to place these prominently in their neighborhood. I am enclosing a copy of the same herewith. We believe that the practice has now been eliminated in the Province of Ontario.

Very truly yours,

P. W. HODGETTS, Sec.

A copy of the placard above mentioned is here given:

#### WARNING!

#### AGAINST SPRAYING FRUIT-TREES IN FULL BLOOM.

The Ontario Bee-keepers' Association desires to draw the attention of the public to the fact that a number of members suffer from persons spraying fruit-trees in full bloom, their bees being killed from the poison in the spraying mixture. This practice is prohibited by an Act of Parliament assented to in 1892, the provisions of which are as follows:

1. No person in spraying or sprinkling fruit-trees, during the period within which such trees are in full bloom, shall use or cause to be used any mixture containing Paris green or any other poisonous substance injurious to bees.

2. Any person contravening the provisions of this Act shall, on summary conviction thereof before a justice of the peace, be subject to a penalty of not less than \$1.00 nor more than \$5.00, with or without costs of prosecution; and in case of a fine or a fine and costs being awarded, and of the same not being, upon conviction, forthwith paid, the justice may commit the offender to the common jail, there to be imprisoned for any term not exceeding thirty days, unless the fine and costs are sooner paid.

The best fruit-growers consider spraying during the period of full bloom as a useless waste of material, and harmful to the setting of the fruit. It is universally condemned by entomologists in every part of America. The recommended formulas, as sent out by both the Federal and Provincial Departments of Agriculture, state distinctly to spray apple-orchards with Bordeaux and some arsenical poison: 1. Just as leaf-buds are expanding; 2. Just before blossoms open; 3. Just after blossoms fall; 4. Every ten days later if required.

Bee-keepers and fruit-growers are both urged to see that this harmful practice of spraying during bloom is stopped.

It is hoped that the law will not have to be applied, as most persons are unaware of the harm that they do themselves as well as the bee-keepers.

Signed on behalf of the Executive Committee of the Ontario Bee-keepers' Association.

F. J. MILLER, Pres.,  
Ealing P. O., London.

P. W. HODGETTS, Sec.,  
Dept. of Agriculture, Toronto.

## BEE-KEEPING IN THE SOUTHWEST

BY LOUIS SCHOLL

There was no spring crop of honey this year. The bees are in good condition, however, and Central and North Texas expect a good summer crop.

The Texas Bee-keepers' Association has over a hundred members. Its next annual meeting will be in July, the dates of which will soon be made known. The convention is to be held at College Station, with the Texas Farmers' Congress. Many very important matters will come up at this time, so plan to be there, if a Texas bee-keeper. Low rates.

A copy of "Southern Bee Culture," by J. J. Wilder, Cordele, Ga., has come to our desk. It contains 150 pages of "Bee-keeping of the South," treating the phases of the subjects in a practical way, with illustrations. Statistics are given showing the status of bee-keeping in each of the Southern States, together with a write-up of the industry of each of these. Texas heads the list, of course!

Southwest Texas, where the bulk of the honey of our State is produced, has reported a very light crop so far. Prospects were never better; but cool nights and rains that prevailed during the honey-flows "cut it off short." The early spring flows are the main dependence there, and the bee-keepers do not "figure" very much on later flows. This is enough to predict a short crop for Texas this year, unless something unusual should happen.

Some people are not so innocent as they pretend. Just so in the case of Dr. Miller, p. 412, regarding who the authorities are that do not believe in painting hives. I do not side with your position if it is as outlined by the editor. In your 40 years of bee-keeping you have changed hives several times already. But what did you do with the old unpainted hives? Threw them away! That is a good argument in favor of painting, for "we-uns" who haven't so much money to throw away. I have changed hives once already in my sixteen years of bee-keeping; and the old hives, which are as good as new, practically, kept so by being painted three times during that period. I am selling off now instead of throwing away. The cost of the painting was gotten out of them in their use, so what I get for them is all profit. See?

### DUMMIES IN THE BROOD-NEST.

Dr. Miller thinks that dummies should be placed in the center of the brood-nest in contraction, since the bees do not work above the dummies so freely when placed at the sides, p. 485. It would not work here during the breeding season; and that extends over the greater part of the year, as we have continuous, long, slow flows—more or less honey coming in, and breeding going on to keep up the strength of the colonies. Now,

those dummies, unless of the right kind (Aspinwall's, for example), would have a tendency to keep the queen confined to the few combs where she happened to be. Even a defective comb in the middle of the brood-nest often keeps the queen from getting over to the other side except during the heavy breeding season, perhaps, when she goes beyond; but her laying is retarded every time she comes to this comb. Wouldn't dummies cause the same results if placed in the brood-nest?

### HIGHER PRICES FOR HONEY.

With a light crop in Texas, the same in California and in some of the other States, as indicated by the reports thus far, I can see no reason why honey should not range higher in price this season than last. 'Tis true that last year's prices were above the average of several years; but then Southwest Texas had at this time already produced and shipped several hundred cars of honey. While it is generally supposed, through reports from a few of the less favored sections of this State last year, that Texas had a short crop, it is a fact that much more honey was produced. In spite of this prices were good, owing much to the increased demand. This increased demand is quite a natural one. People here are beginning to know more about bees and honey, and the use of it. Many families use more honey now than formerly, also, and this number is increasing. Of course, the pure-food laws have had an effect.

### PREVENTION OF SWARMING.

One of the main secrets (?) in the prevention of swarming is that of providing plenty of clustering room early in the season so the bees may not become crowded. The next is that of preventing a solid mass of sealed brood from developing in the brood-nest by spreading brood and inserting empty combs at the right time, thus providing laying room for the queen. Neglecting this is the most common cause of swarming fever. This congestion of sealed brood is difficult to prevent in deep hives unless combs are handled—empty ones exchanged for full ones, etc.; but in the production of extracted honey it is not so difficult, for the reason that extra super room can be given early in the season. However, the brood-nest must be watched in order that the crowded condition may be prevented, as such colonies often swarm even if there is plenty of room around the congested combs of sealed brood. A colony in this condition would swarm if it were domiciled in a large drygoods-box with plenty of empty space around it. The point is to break up this solid mass of brood.

W. H. Laws, of Beeville, Texas, places a body of empty combs on each colony early in the season for clustering room. Later, when the brood-nest assumes the condition above, the empty combs are used to replace half the combs in the brood-nest below, alternating the empty ones with those containing brood. The upper story is then arranged the same way, with the combs of brood taken from below, and the empty ones left in the super. This done at the right time knocks swarming in the head. If any of the colonies get strong enough to swarm after this manipulation, the upper story is removed to a new stand for increase, and additional room provided. It

is useless to try to prevent colonies from swarming after they have already gotten the swarming fever or have started cells. Such colonies are shaken (shook swarming), and their combs used for other purposes.

In comb-honey production it is much more difficult to manipulate the regular-depth L. hives. Almost all the manipulations necessitate the handling of combs, requiring a lot of labor and time. I have found the shallow-hive system a time and labor saver. An extra shallow super can be placed on the colonies much earlier in the season than a deep one. When the main honey-flow comes this which was used for additional breeding room is filled with extracted honey. Just before the swarming period, another shallow story with empty combs is slipped in between the two lower ones containing the brood-nest—a solid mass of sealed brood generally—thus breaking this up, and providing additional clustering and breeding room. This prevents swarming with us, and insures rousing colonies for the main flow. The comb capacity is then equal to 24 L. combs, all occupied.

When the comb-honey supers are put on they are placed under the upper shallow extracting-super, which is now full. There is no sealed honey, or very little, along the top-bars of the brood-nest, above which bees are loath to store. They are used to working above, and with a full super on top they go to work with a vim to fill up the empty space in the comb-honey super. Much better work is done under these conditions, and the colonies are such rousing ones that the yield must be larger than that from those managed on the plan generally followed. Furthermore, an extra super of extracted honey can be counted on as just so much more profit.

## FANCIES AND FALLACIES

By J. E. CRANE

The quotations of the price of honey and wax in foreign markets is of decided interest to us, although we may have no honey to ship to Liverpool or Paris.

Mr. Fritzche, you look very happy among your bees, p. 288, and those sheds certainly look very comfortable this cold windy spring weather; but, say, "don't it nigh a'most" break your back to work your hives under those sheds?

"Honey from combs not yet bred in can generally be distinguished easily by the taste from that which is extracted from dark brood-combs"—Stray Straws, p. 275. Perhaps one person in five hundred can; but who ever heard of a buyer of extracted honey finding fault because it was extracted from old combs?

That "buttermilk honey," page 277, reminds one of some counterfeit bills in the Bureau of Printing and Engraving at Washington, where a bill is executed or printed, so to speak, with a

pen; and the same amount of time and industry in a legitimate way would have paid far better even had the counterfeit bill been worth its face value.

On page 275 V. Wuest is quoted as saying or thinking "there is no proof that the nectar of poisonous plants is harmful to bees." I was told many years ago, while in California, that in some parts of the State bee-keeping did not pay, as the buckeye, when in bloom, poisoned the bees. Plants that poison one class of animal life are or may be harmless to another. Aconite is very poisonous to man, but harmless to sheep; and swine are said to thrive on rattlesnakes.

On p. 349 Dr. Miller gives some advice to beginners in the production of comb honey. I can not tell how much it would have saved me to have had some such advice when young in the business. But say, doctor (I should not like to hurt your feelings—no, not for a good-sized doughnut), wouldn't it be better to advise beginners to begin with such sections and separators and bees as will give solid combs rather than to have to bother with two pieces of foundation in each section?

Dr. Miller says, p. 336, that he does not want to believe that bees are unusually long-lived just because they are lazy. Well, he need not believe it. Men are not long-lived just because they are lazy; and horses—don't you know some that will work harder and live longer by far than others? Constitution, strength, longevity, play quite as important a part with our bees as with other races. Don't we all know of colonies with a fair amount of bees and a sufficiently prolific queen that will but little more than hold their own during a season, while others no more populous, with a queen to supply them with eggs, will build up beyond our most sanguine expectations? The last will increase while the first will barely keep the same strength. How can we account for it, except far greater vigor and consequent longevity? It certainly is not in consequence of laziness.

When yellow bees fail to winter well, Mr. Alexander advises that two combs of honey be taken from their hives Sept. 1, to give the queen room for brood. Now, in more than forty years I have never known bees to be crowded for room at this season. The surplus with me is practically all gathered in June and July, while Mr. Alexander's best flow of honey comes in August. While his hives are crowded by September, therefore, my own are sometimes almost in a starving condition, and never need to have combs removed to give room for brood. I believe Allen Latham's views on spring feeding, pages 358 and 359, as well as those that follow, are quite right, and extracting honey in May should be limited to those seasons when there is a great abundance of honey coming in and the brood-chamber crowded, when the extractor may be used to advantage. I suspect that the greater flow of honey at Delanson during the early season is the only reason for the difference of opinion as to the advisability of extracting.

Another thing in this connection I will mention at the risk of being thought heterodox. All advise feeding early enough so fall-fed stores may all be sealed before cold weather. This would necessitate feeding in this latitude early in September; yet I rarely begin feeding before October, and find few or no bad results. The yard that I fed last (after the middle of October) last fall has wintered best. I do not think one-fourth and I doubt if one-fifth of the syrup fed was sealed, and yet that yard has wintered the best of any of my yards—in fact, perfectly, with a loss of only one colony, and that worthless in the fall. Doubtless to feed early enough to get feed all sealed may be best or ideal; and yet let no one feel that, because he has failed to do so, serious results will necessarily follow. I only wanted to say that I think more emphasis has been laid than necessary upon the need of having all stores sealed.

On page 285 is a picture of as fine-looking a lot of bee-keepers as we often see, and yet on the next page Mr. Holtermann tells us that, in convention assembled, they "resolved themselves into a series of hostile camps, being hot and cold 'processors,' thick and thin 'syrup-makers,'" etc. Well, now! They must have had a live topic; but, alas! all the argument and discussion in the world can not settle these questions. Whether the best results can be had by feeding sugar syrup thick or thin, hot or cold, slow or fast, with inverted syrup or otherwise, can be shown only by careful experiments. Why should sugar syrup need to be inverted? "I don't know." Does it make it more healthful food for the bees, or is it for the purpose of preventing granulation? One thing seems certain: If the bees are provided with a special organ in their mandibles for providing an acid for this very purpose, it must be of considerable importance.

On p. 281 is an article from the pen of E. W. Alexander, of unusual interest, as it shows how differently we must manage bees under different environments. He says, concerning Italians, "Their never satisfied desire to gather honey causes them to fill their brood-nest early in the season;" and so he advises removing this surplus of honey so the queen can fill the brood-chamber with brood. Now, such advice would be the worst that could be given me, for rarely do the bees fill their brood-chamber with honey, and the bees need all the honey in their hives for rearing brood, and frequently have to be fed in addition to what they have or gather. In only two years in over forty have bees crowded their brood-nests with me before clover bloom—once from maple bloom and again from apple bloom; and when such was the case the treatment which Mr. Alexander advises is the best possible. If he errs it is in thinking others enjoy as good a location in springtime as he.

On page 350 a paragraph is quoted from the *Prairie Farmer* on the use of honey as a food. In the last sentence it says, "The only obstacle in the way of its more general use appears to be that many people can not eat it without stomachic pain." The editor of GLEANINGS thinks the

editor of the *Prairie Farmer* away off, and gives us to understand that the stomachic pains come wholly from overeating of honey. Did you ever! Now, if the editor of the *Prairie Farmer* had said that "some persons" instead of "many persons" can not eat honey without stomachic pain he would, I believe, have stated the exact truth; and had the editor of GLEANINGS said that as many or more persons are made to suffer from overeating of honey as from any peculiar quality of honey he too would have hit the nail square on the head. Had he also stated that, where honey causes any disturbance of the stomach, whether from overeating or otherwise, a drink of milk will usually bring immediate relief, it would have been helpful.

---

## CONVERSATIONS WITH DOOLITTLE

---

### BEES CHOOSING A HOME.

Several years ago, during one season I had three swarms come out, each several days apart; and as soon as all were out in the air they started right off without clustering; and all of my drumming, slinging of water, dirt, and such like, did not stop them. I used to scout the idea that bees looked out for a location before swarming, or while clustered for that matter. I thought they just wandered until they found a place. A year or two after the swarms I spoke of went away I saw bees going in and out of a crack in the siding of the house just under the plate on which the rafters rest, and I thought there was a colony in there; but upon opening a door to a small cupboard there was at that place in the house I found nothing. The next day the bees were there again; and about noon, as I was going to dinner I heard the roar of a swarm, and, upon looking up, thousands of bees were pouring on to the house and running into that crack. This thing continued for some minutes. Upon opening the door that night I found a nice swarm had taken possession of that cupboard. After this I put out hives and boxes all about the premises, in places where I thought the bees might like a home. I have watched the bees going out and in, cleaning up these hives and boxes in an eager and excited manner; and from a day to two weeks I have had swarms come and go into these cleaned places. At times I have seen the scout bees, as I call them, at work, and the next time I came that way I have found the swarm housed and at work. Can I doubt any longer, when, for the past four years, I get in this way each year from four to twelve swarms? I know now that these scout bees lead the swarm to the selected place.

Iowa.

I should have left this letter in its pigeon-hole had it not been that, on pages 1508 and 1554 of GLEANINGS for 1907 the editor says that he would be glad to hear from others on this scout matter. On pages 1507, '8, Mr. Greiner gives us some very interesting matter on the subject of bees choosing a home, and seems, on the whole, to come to the conclusion that these scout bees are sent out by the swarm as a "matter of compulsion" while the swarm is on the limb, rather than that they go out before the swarm leaves the parent hive to choose a home, so that the swarm knows where it is going before it leaves its old location. But, as Dr. Miller points out on page 1553, I do not see how he could arrive at such a conclusion after telling us that he saw these scouts at work the afternoon before the swarm came. But if I were one of those scouts, sent out from a swarm, I think it would be compulsory with me if I went at all, for I should never expect to see either my old home or the swarm again, but to die a homeless, starved, and chilled wanderer the next night after I went out, especially if my old home happened to be in a modern apiary. Why do I say this? Because if a swarm is allowed to hang

on a limb long enough to send out scouts, these same scouts mark their location from where the swarm is, and forget all about their old "parental roof." Very many times I have hung the clipped caged queen, with a swarm of bees, when I was not just ready to care for them as soon as they were clustered; and if thus left for an hour or more, there would be from ten to one hundred bees hanging around the place where the swarm had clustered, within an hour after it was cared for. The bees would stay there all the rest of the day, flying about in a lost condition, and occasionally rest on the limbs and leaves near by, clear up to nightfall, and in a very few instances I have known of a few of them being there during the next day, when the night was very warm.

Here is something about the swarming of bees that I have never seen in print, even if it has ever been noticed before by any one. Why any bee should entirely lose the location of the old home, when being sent out as a scout, is something which I can not understand; but I am quite sure that they do, for I have found them lifeless the next morning on the leaves and limbs where the swarm clustered, after a cool or cold night. Another thing pointing to such a conclusion is this: One day, just after a swarm had clustered, an urgent call came for me to go away for a little time. I hung the caged queen with the cluster and left them. I was obliged to stay till into the afternoon. On arriving home I prepared a hive and was about going to take the bees when they began to break cluster for leaving, and all went off out of sight, leaving the caged queen hanging there. As I always let three or four bees run with the queen into the cage when I am caging her, to care for her should any unforeseen thing happen, I knew she was all safe, so I did not disturb things at all, only to see that every single bee of the swarm not in the cage had gone. I was all interest to know just how this thing would come out, as it was something that had never occurred before in all of my bee-keeping life. The seconds passed into minutes, till ten, fifteen, eighteen, and twenty of them had passed, and I had almost come to the conclusion that I was out that swarm all but the queen, when I heard them coming back. I was now more curious than ever to know where they would go; whether to the limb from whence they went, or back to their old home; so I went to the hive, expecting to see a part of them, at least, return home. But, no, sir; not a single bee went back to the hive; but they clustered on that limb the quickest I ever knew of a swarm clustering in the world.

Now I am sure that swarms send out scouts while they hang on the limb, from the number of bees hanging about the clustering-place after a swarm has hung some time; for if the swarm is taken care of just as soon as the bees are clustered, or if the queen is held from them so that they return to their old home after clustering, none of these scout bees will be seen hovering around all day. The queen *must* be with the swarm, and the swarm hang some time, else the scouts will not be sent out. I have dwelt on this part of the matter more at length than I otherwise would because of this sentence from Dr. Miller: "I am strongly of the opinion, buttressed by much observation, that bees generally send out scouts before rather than after swarming." And I also am

equally sure that they send out scouts before swarming, and, as Dr. Miller says, "for several days;" and if he had put it several weeks I would not object. I will give only two of my many observations. The first was like this:

I put a hive in a tree at the side of the apiary for some squirrels to nest in, which came down from the woods near by. They built a nest and stayed till spring. One day during the swarming season I happened to look up at this hive when I saw bees going in and out at the hole I had bored for the squirrels, which led me to believe that a small swarm had taken possession of this hive. A neighbor had requested a small swarm for his boy, and so I told him I had it for him if he would get the hive from the tree the next morning. He came early, got the hive down carefully, so as not to disturb the bees, when to my chagrin, there was nothing but the squirrels' nest in the hive. At my request he put the hive back, and by ten o'clock that day the bees were going in and out at the squirrel-hole as thick as ever; and by careful watching I could detect now and then a shred of the nest taken off by some of the bees flying out from the hole. This was kept up for three days more, when we had two or three days of bad weather, during which I saw no bees at the squirrel-hive. Two or three days later it came off fair again, and the work went on at the squirrel-hive, and, one day later, a swarm commenced to issue from a nearby hive, and, to my surprise, they went right out from their entrance into the hole in this squirrel-hive, scarcely circling about at all.

The second, and the most exasperating of any of the very many scout cases which have come under my observation, was like this: An old bee-hunter came to me one day the latter part of June and said he had found a bee-tree, and wanted me to help him cut it in the fall so we could save the bees. He told me it was a big hard maple with a hole in the side of it forty feet from the ground. Passing that way two days later I looked at the hole and saw many bees going in and out of the same, so I took it for granted that he had tracked bees to the tree. One wet afternoon in September he came with a dull saw and ax for me to go with him to cut the tree. We took all that was necessary to get the bees and honey. To make a long story short, it was after four o'clock when the tree came down, and my hands were so blistered that I could hardly work the smoker, which we had going for an hour or more. Rushing up to the hole with the smoker to keep the bees from pouring out, not a bee was seen, and, what was more, not a bee could be heard. Ten minutes sufficed to "slab" off the side above the hole, when we found a cavity all nicely cleaned, but not a single bee, either dead or alive. Upon questioning the man closely he said he went by the tree two days before he told me of it, saw the bees going in and out, the same as I did, and was sure he had a bee-tree.

---

ARE BEES REFLEX MACHINES? in the Italian language is now being published serially by *Apicoltura* of Milan. The translation is from the English edition now appearing in GLEANINGS. The translator is V. Asprea, of Calabria, Italy.

## GLEANINGS FROM OUR FOREIGN EXCHANGES

By W. K. MORRISON

With reference to Italian bees, I note some of the Swiss breeders around the Lake Maggiore mountain region claim to have the best strain of these bees, or what we term in this country the leather-colored Italian. It seems to me this is so, and some of the breeders on the lowlands advertise their bees as descended from that stock.

The Belgian journal, *Le Progress Apicole*, in a recent number prints an article by the editor, wherein he states that, on August 26th of last year, he saw a great many black bees working on violet (red) clover. He saw more of them thus engaged than he did of Italians and their crosses, though the latter are quite plentiful around there. Just score one for Dr. Miller's irascible blacks.

The *British Bee Journal* for April 16, 1908, contains a fine portrait and sketch of the career of Mr. Edward Bertrand, the well-known editor and author who did so much to popularize the Langstroth system of bee-keeping in Europe. His journal, the *Revue Internationale*, was a model of what a bee paper ought to be; and his book, "Conduct of the Apiary," has had an excellent sale, having been translated into six languages. He translated several other works from English into French, notably Mr. T. W. Cowan's books. He lives now in retirement at Nyon, Switzerland.

President Kramer, of the Swiss Bee-keepers' Association, has just issued a new book, "Die Rassenzucht der Schweizer Imker und die Amerikanischen Zucht Methoden." Taken all together it is the best work on queen-breeding I have seen. It contains a wealth of beautiful illustrations. The printer has done his part to perfection; and the paper and general *ensemble* leave nothing to be desired. President Kramer is broadminded, and gives America its due in respect to many little discoveries and inventions having to do with queen-rearing. This makes up a book of 168 pages, octavo size. It has the last word on queen-rearing, and it will be difficult for the next writer on this great little subject to surpass it. Such a book from so small a country makes we 'uns look *small*. The publisher is Paul Wassel, in Freiburg (Baden). Price 50 cents.

We do not monopolize the correspondence-school business by any means; for I recently received the catalog of a bee-keepers' correspondence course of instruction issued by Mr. P. Peters, of Baud, in France. During 1907 nearly 200 students took the course, and, so far as one may judge from a synopsis of the lessons, the studies must be of considerable practical value. Aviculture is also taught at the same place, the idea of the founders being to instruct students by mail in the small industries connected with agriculture. France for many years led the world in poultry culture, and even now is not much behind the United States. The French farmers excel us in the production of really superior table

fowls. The Peters school also supplies a course in arboriculture—a very interesting and practical subject, and one that ought to receive more attention in this country.

For more than fifty years lectures on bee culture have been given in the gardens of the Luxembourg, at Paris. The first lecturer was the famous Hamet, who founded the well-known Parisian bee-journal *L'Apiculteur* in 1856, and which is one of the best bee publications in existence. The present editor, Prof. Sevalle, is now the lecturer. The lectures are free to all.

The Parisian contemporary of GLEANINGS, *L'Apiculture Nouvelle*, contains in the April number an account of the principal bee-plants of France. The first is sainfoin clover, that celebrated standby of the European bee-keepers. It is very extraordinary that this plant has never been boomed in this country as a forage-producer, though it is one of the best known. It is not as heavy a yielder as alfalfa, but the hay is superior, and it produces a full yield of nectar wherever it is grown. Rustic alfalfa is also mentioned as a good honey-plant. This has been grown in Michigan to some extent. Perhaps this is the right kind for Ohio, Indiana, and Illinois. Buckwheat is mentioned as being grown extensively in Brittany, Auvergne, Morvan, and Bresse. I am under the impression that buckwheat is often used in France to feed poultry, and Bresse is justly celebrated for its fat chickens.

One of the European bee journals recently gave map illustrations of the distribution of the bees of the world belonging to the genus *Apis*. This included practically the whole of South America. As a matter of fact, there are none of our bees in the great valleys of the Amazon and Orinoco—not a single colony. There are honeybees, originally from Spain, in the highlands of Colombia and Venezuela, but the stingless bees in myriads occupy the great river valleys. Our bees, when introduced, soon die out. Their enemies are too numerous. Prof. Frank Cheshire fell into the same error as our German contemporary. South America has native bees that sting, but they are very different from *Apis mellifica*, and were there long before Columbus sailed from Cadiz in 1492. *Apis mellifica* bees are quite common in South Brazil, Uruguay, Argentina, Chile, and Western Peru, where the conditions are more favorable.

I have received a copy of the anniversary number of the Manila *Daily Bulletin*, sent out by the publicity committee of the Manila Merchants' Association. The number now before me is a remarkable tribute to American enterprise. Its 78 pages are twice the size of GLEANINGS, and it is beautifully illustrated with many half-tone engravings. It is chiefly devoted to showing the agricultural features of the Philippine group. There are fine articles on the forests, fruits, fibers, orchids, oil-plants, nuts, starch-plants, and railways and water transport. Most of the information would be a revelation to many Americans—at least 95 per cent of them. Any one who has a notion of trying colonial tropical life ought to send for a copy. Price 34 cents.

## EXTRACTED - HONEY PRODUCTION.

### Uncapping the Honey.

BY W. Z. HUTCHINSON.

*Continued from last issue.*

It is possible that the California plan of melting the cappings as fast as shaved off may prove the most desirable plan; but, so far as my experience goes, I have found nothing better than letting the cappings drop into a cracker-barrel set over a tub. Some grocers give the barrels away, if you are a customer; some ask five cents apiece for them, and I never paid over ten cents. The cappings can be allowed to stand and drain for weeks and weeks—no hurry about the barrel; simply pay ten cents for another one.

I bore three or four holes in the bottom of the barrel for the honey to run out. This may not be

LAMP STOVE THAT KEEPS THE UNCAPPING-KNIFE HOT.

Honey extracted in hot weather, soon after it is gathered, may not require a hot knife for its uncapping; but to uncup in the cool weather of the fall, honey that has been on the hives all the season, a hot wet knife is almost a necessity.

necessary, as such barrels are not water-tight; but it is a wise precaution to be *sure* there is a place for the honey to get out. Then I nail a wooden cross-piece just inside the top of the barrel; but before nailing the cross-piece in place I drive through it a ten-penny nail; and when putting the cross-piece in place I turn the point of the nail upward.

In uncapping a comb the end of the frame is rested upon this nail-point, which comes as near being a universal joint as any thing with which I am acquainted. The frame can be turned "every which way," and it will not slip about. The barrel is supported over the tub, or slightly below the top, by means of double hooks made of heavy wire. In the accompanying engraving one of these hooks is hung outside, upon one of the handles, to show its shape and make-up. Four hooks are used, placed equidistant around the edge of the tub, and the barrel lowered down upon them, the hooks catching just inside the "chime." There is still another plan of supporting the barrel that has the advantage of furnishing handles with which to lift the barrel, and that is to nail two slats of wood to the sides of the barrel, about four inches from the lower end. The slats are nailed to opposite sides of the barrel, at right angles to the staves, and are long enough so that the ends rest upon the upper edge of the tub. The only objection to this plan is that the ends project out slightly beyond the edges of the tub, and are just a little in the way.

After the honey is off the hives, and warmed up, the biggest part of the remaining work is that of uncapping the combs. If they are thick and "bulging," they can be uncapped much more easily. If only eight combs are used in a ten-

CRACKER-BARREL FOR AN UNCAPPING-CAN.

After a barrel is full it can be set to one side, over a tub; or two or three barrels can be stacked up, one on top of the other, and allowed to drain for weeks. The cappings can be brought home, or even shipped by freight, right in the barrels.

ONE OF THE HUTCHINSON APIARIES IN NORTHERN MICHIGAN.

frame super they will be of this class, when, by cutting deeply, so as to leave the combs only about one inch thick, each side can be uncapped with one "fell swoop." It was hard for me to get over the feeling that I ought to uncup as thinly as possible—that thick cappings were like thick parings from a potato—but it really makes little difference whether the honey goes through the extractor or drains from the cappings.

To do the best work when uncapping, the knife ought to be sharp, hot, and wet. Only the man who has tried it can realize the difference between such a knife and one that is cold, dull, and dry. I have a little two-burner oil-stove standing upon a barrel at my elbow, and upon the stove a tin or pail filled with water. When through uncapping a comb I simply lay the knife in the hot water, as it is just as easy as to lay it down somewhere else. When I begin uncapping the next comb, the knife is hot and wet; and the way it will slip through the comb is a caution. If this management did not keep the knife hot enough, then I would use two knives, leaving one in the hot water while using the other. When heating up the honey with the Perfection heater, we found that we could dispense with this small stove by using two pails of water, leaving one on the Perfection heater, while the other sat upon the barrel at the side of the operator. When the water became too cool we simply changed places with the pails.

Very new combs or very old ones do not uncup as easily as those that are between the extremes. An old comb that has recently been drawn out thick—that is, the bees have lengthened the cells, partly with new wax and partly with wax taken from the old comb, is about the nicest comb to uncup. The lower part of the comb has a stiffness or stability, while the upper part has sufficient softness to make it cut easily. A man can afford to go to a lot of pains and expense to get exactly the right kind of combs to use in his supers—old combs spread wide apart—as the saving of time in uncapping is very important.

To uncup a comb, rest one end upon the nail-point of the cross-piece over the barrel. Stand the comb in a nearly upright position. Hold it with the left hand, grasping it near the upper end. Begin at the lower end to uncup, giving the knife a sort of slanting, shaving movement, such as a barber gives his razor, drawing it back and forth as it cuts its way upward, at the same time slanting the comb slightly forward (toward the knife) so that the cappings, as they break off, will drop into the barrel instead of upon the surface of the comb.

#### THE EXTRACTOR.

I have used the two-frame reversible and the four-frame automatic reversible, and I have seen the eight-frame automatic in use when run by a gasoline-engine. My preference would be the four-frame automatic. It is certainly worthy of all praise. The brake, the automatic reversing of the combs, the ball-bearings, are time-savers and great comforts. The machine is inclined to run more steadily than the two-comb machine. There is less of that wobbly motion if the combs vary in weight. Power is needed to run the eight-comb machine; and, as the only object in using this machine instead of the four-comb is to save time, I doubt the expediency of employing

it, and the attendant power, in the plan that I am following. There is no special hurry to get the extracting done, as when fewer supers are used and some of the combs must be emptied to give the bees room. To run the eight-comb, with power, requires a crew of men to work to advantage, while one man can work very advantageously with the four-comb; or two can work together to very good advantage. If I were to adopt the eight-comb and power, I would get only one extractor and one engine, and then move them from one yard to another, as the work was completed at each yard. This, of course, would require a team, while I am trying to work out a system in which there is no transportation from one yard to another during the entire season, except that of the man who does the work.

The manner in which the extractor is set up to do the work will depend upon the surroundings. We have three extractors, and each is set up in a way different from the others. Where we extract in the cellar the extractor is set nearly a foot above the floor, and then a hole, or pit, nearly two feet deep is dug, in which to set the strainer-tub and cans to be filled. Of course, the sides of this pit are boarded up. At another apiary the honey-house is built over the cellar, and here the extractor stands directly upon the floor, the gate being placed over the hatchway, the straining and canning of the honey being done in the cellar. The honey runs out of the gate, falls down through the hatchway, and drops upon the strainer below. At the other yard a solid platform, nearly three feet high, is built in one corner of the honey-house. This platform is large enough for the extractor, for the man to stand who turns the crank, also for one or two supers of combs to stand, side by side. An extractor at this height from the floor allows room for the strainer, and for a man to stand upon the scales below the honey-gate of the strainer-tub.

*To be continued.*

## DR. MILLER AND THE USE OF QUEEN-TRAPS.

### Their Use and Abuse.

BY R. L. TAYLOR.

For the purpose of discussing queen-traps and clipped queens, Dr. Miller starts out with what purports to be a quotation from an article of mine on the subject, as a text. He has evidently made the quotation from memory, and, relying on that, his memory has played him false. The language he chiefly criticises is not to be found at all in the paragraph which he ostensibly quotes; even the subject of queen-traps, which is his main topic, is not mentioned in that paragraph at all; yet these phrases, with some correct quotations, are thrown together with comments of the editor and remarks of his own, all duly marshaled under quotation-marks, proclaiming "this is a literal quotation."

Beginning with the above paragraph I set out to reply to the article by Dr. Miller on page 556, and it was followed by a mild criticism of his method of making quotations. Since writing, however, I have been informed that the doctor was in nowise responsible for the quotation-marks,

nor for the mention of my name in connection, but that the proof-reader has to bear the blame. The doctor, therefore, is entirely exonerated, he having simply paraphrased what I had said and what the editor had said I had said. The doctor's fault is, I think, that he should have realized that a paraphrase of a paraphrase stands a small chance of doing reasonable justice to the original. Even so I am not averse to following him through the refinements of his discussion.

He first attacks an expression found in the assumed quotation; viz., "For queens are likely to be superseded at any time, for any cause, without the knowledge of the apiarist. Concerning this expression he asks whether it is not slightly overdrawn. Well, perhaps it would be misleading if readers had little or no knowledge of the habits of bees. But I always feel a strong hesitancy about entering into details of which my readers have as much knowledge as myself. Who of my readers would think that sentence was to be understood as intimating that bees were likely to supersede their queens in winter? or who but Dr. Miller that they were as likely to do it in May as in August? Were I to say that in this locality it is likely to rain in January, who would suppose that I meant to affirm that it was as likely to rain then as in April? But, after all, that was not my language at all; what I actually did say was simply this: Queens are superseded; accidents happen to them, sometimes. Is not that harmless enough?

Again, how is it possible for the doctor to understand from "page 19" that I meant to affirm that "the new queen, after she gets to laying, is likely to go off with a swarm"? In our former controversies Dr. Miller had sometimes resort to the assertion that I was unfair. I have no inclination to retaliate in kind; but, rather, I feel as Job may be supposed to have felt after his adversary had written a book, if the old version of him is correct; for did he not exclaim, Oh! that mine adversary had written a book? If I am misrepresented I only ask a fair hearing—then let the record declare judgment. But, to return to the point: Does not every bee-keeper of any experience know that a colony, even if of only fair strength, having young queens emerging during the swarming season, either on account of superseding or for some other reason, will generally cast a swarm? and do they not know that the swarm is always led by a virgin, not a laying queen? The first swarm I had last season was led by a virgin queen, and it was not a solitary instance.

Further on he asserts that I practically say, don't clip, but put a queen-trap on each hive, etc. How could the doctor make that assertion? Perhaps the editor is partly to blame, for the quotation in GLEANINGS does not at all bring out the points in my argument in favor of the trap. It might have been an advantage to the doctor had

WAYNE PAVILION, OR SUN PALACE, WHERE THE NATIONAL BEE-KEEPERS' CONVENTION WILL MEET, OCT. 13, 14, 15, 1908.

he had before him the article from which the quotation was taken. I should have been glad to furnish him with a copy if only that he might have correctly stated the restrictions which I would place upon the use of the trap. What I do say is, don't clip; let the bees swarm naturally when there can be an efficient attendant; but when such attendant can not be had to care for the swarms, then use traps to be visited every three or four days, for traps will prevent all absconding, while clipping will by no means do that. Clipping a queen prevents her from leading off a swarm; but when she is lost or killed, as she is likely to be soon if not cared for, it is but a question of a few days when a young queen will emerge, and in all probability undertake to escape with a swarm.

The trap, of which the doctor makes so much, is not even mentioned in the quotation on "page 19," but the doctor is after the trap, and asks whether it would not be natural for some readers, at least, to put on traps in the spring, leaving them thinking that thus the matter was settled for the year, thus destroying the unmated queen, and, through that, the apiary? No doubt, no doubt. I have known of cases of bee-keepers clipping unmated queens.

As a result of his neglect to secure and read my article from which the extract on page 19 is taken, the doctor falls into the error of appearing to attempt the riding of two horses at the same

time, by criticising my method of managing swarming without clipping, on account of the necessity of sorting out queens from united swarms, on the one hand, and, on the other, criticising what he supposes, apparently, to be my advice and practice in regard to the use of the trap, as though I used at the same time both the free-flying-queen system and the queen-confining-trap system on the same colonies.

The doctor seems at a loss to understand why a queen in a trap through which a swarm has just passed should be more effective in recalling the swarm, or, in other words, in putting them on their good behavior, than a queen hopping about on the grass, and asks for a reason. The reason seems plain; a queen hopping about on the grass has no abiding-place. Generally for some time there are few or no bees with her, and the bees are not inclined to look for her in the grass; but when they fail to find her in the air they naturally seek her at the hive, where they last knew her to be; and as she is there with a retinue, the swarm, if in the air, is soon notified, and returns more promptly than they would if she were not so found. In other words, they discover their queen more quickly, and so have less time and opportunity to unite with other swarms. But I may not understand on just what point the information is sought. It may be with reference to the matter of swarms uniting and entering

other hives than their own. In answer to that I should say that, in addition to the above, I make no claim of advantage for the trap in that respect over the clipped-queen system. But remember, it is not traps against natural swarming with an attendant, but traps against clipped queens in cases where there can be no attendant. I can't be sure; but I rather guess that, if the doctor were taken suddenly ill, or called to a distant wedding or funeral, in the height of the swarming season, with no possibility of obtaining any one to look after his bees, he might, possibly, remember traps with a certain longing; or would he prefer to trust to clipped queens?

In a nutshell, when there is an attendant the doctor prefers clipped queens during swarming. I prefer the queens unclipped on account of the more rapid settling of the swarms and the increased freedom from uniting and from the entering of strange hives. When an attendant is wanting I prefer traps, because in such a case they are the best security against the loss of bees, but they should have attention twice a week. In such a case the doctor prefers—?

Lapeer, Mich.

[As Mr. Taylor intimates, Dr. Miller was not responsible for the quotation-marks inclosing his first paragraph on page 556, May 1st issue. Owing to a difficulty with eyesight, as explained editorially on page 683, last issue, we did not discover the presence of the aforesaid marks. When Mr. Taylor sent in his article he very naturally inferred that the doctor was misquoting him, and very properly called him to account. When we explained the matter to Mr. Taylor, he exonerated him and substituted other paragraphs.—Ed.]

## WOOD SPLINTS PROPERLY APPLIED SUPERIOR TO WIRE.

### How to Prepare and How to Apply.

BY B. F. AVERILL.

I note Dr. Miller's article in April 1st GLEANINGS; and as I find wood splints, properly applied, to be superior to wire, I will submit my plans. I am not asserting that any of the ideas advanced are better than those hitherto given, but they may be found more practicable by some operators. If the plan of using splints is coming into more general use, the best possible methods of application should be put forward at as early a time this season as possible in order to give bee-keepers a chance to test them.

My plan of using the splints incorporates them with the frames as well as with the foundation; and thereby I secure a more substantial comb than if incorporated only with the foundation.

The first essential part of the plan is to have top and bottom bars grooved in the center to receive the ends of the splints. A saw-kerf  $\frac{1}{8}$  gauge

JOHN BAILEY'S DISPLAY OF HONEY AT THE BRACEBRIDGE EXHIBITION. ONTARIO, CANADA.

and  $\frac{1}{8}$  deep is the most suitable dimension to adopt. The splints should be  $\frac{1}{8} \times \frac{1}{8}$  or  $\frac{1}{8} \times \frac{3}{8}$ . The latter dimension is better for splints properly built into combs on a good flow of honey.

The splints are  $\frac{1}{4}$  inch longer than the distance between the top and bottom bars, inside measurements. Waxing is best, but may be dispensed with in a good honey-flow.

To wax the splints, take a dozen or two at a time between the fingers and twirl them in a vessel of hot wax. A little practice will develop the requisite skill. It is not necessary to wax the *entire length* of splints. There will never be any gnawing of foundation around the splints *near the top-bars*. It is at the bottoms of combs being built that all the cutting-out is done.

So you can leave two inches at one end of the splints safely, and the waxing is a small job comparatively. Just stand the splints on end in a leaning position until you have enough supplied for the foundation to be used that day, or a week or month later.

Now, in putting in the foundation you have two inches of unwaxed splint to handle them by. Take hold of this portion and insert the waxed end in kerfs in the bottom-bars, and *spring* the splints into the top-bars. That is the whole process. Now, by using eight splints there is no need of *fastening* foundation to the top-bars. This saves much time, and all that is requisite to success is to be *sure* the foundation fits *close* to the top-bars. If bottom-bars are not of good thickness to support the weight of heavy combs, there is going to be sagging sooner or later. I would advise gluing in a splint to the top and bottom bars through the center of each frame. This unites the top and bottom bars at the center of the combs, and no sagging of combs is possible.

For imbedding splints I use a small wooden roller. Imbed the foundation by placing the splints on the bottom of the foundation and the

roller on the top. It is easy work compared to wiring, and a much greater amount of foundation can be stayed in the same length of time.

I wire many frames for purposes that I can not take room to explain. I am situated so as to make a pretty accurate estimate. As regards wiring, I find the principles of application generally faulty. It is reasonable to suppose that the greatest strain upon foundation occurs near the top of the frames; hence here is the proper place for applying the maximum support. I never use more than three horizontal wires, and not 25 frames in 1000 show the least sign of stretched foundation. My first wire is placed  $1\frac{1}{4}$  inches from the top-bar; second wire,  $1\frac{3}{4}$  below the first wire; third wire,  $2\frac{1}{4}$  below the second wire, and  $5\frac{1}{4}$  below the top-bar. The foundation *below* the third wire from the top-bar is not going to stretch; and if all wires are put in reasonably tight the foundation will not stretch anywhere in working.

I have been wiring combs over 30 years, and have used splints 23 years. I like wood splints the best, but wiring is good enough, though it takes more time.

Howardsville, Va.

[The question may arise whether it would not be advisable to use a combination of wire and splints. Three or four horizontal wires stayed up through the middle by one or two wooden splints might retain the advantages of both systems. Who has tried it?—ED.]

---

*L'Apiculture Nouvelle* mentions the fact that Serbia now has a bee journal edited by Mr. Christophe Mechoulya, and published at Belgrade. Our Austrian friends have done a great deal to improve the agriculture of Serbia, and that the country, small as it is, supports a bee journal, shows some one is doing good work for apiculture.

### A NOVEL HONEY EXHIBIT.

#### A High-class Business Deserves a High-class Display.

BY JOHN BAILEY.

The reason why I like to make a good exhibit or display of my bees, honey, and wax is because it helps to advertise my business, because it introduces honey to the public, and because it helps to sell *my* honey. It also helps to increase the gate fees at our exhibition. Part of my exhibit is not visible, such as the observation hive and the tin and glass packages, of which I had about fifteen different kinds. The wax horsehead on top was made in a mold, as were all the cones, etc. I like to have the display of honey high enough to show above the heads of the crowd of people. A white background shows the honey well if it is put up in glass, and not too close together.

Bracebridge, Ont.

### MAKING INCREASE.

#### The Somerford Plan Modified; the Alexander Plan not a Success During Apple-blossom Time.

BY J. A. CRANE.

When I wish to use a colony for making nuclei I remove the queen as directed in the May 1st issue, page 577, placing her in a cage on top of the frames. I leave her there three days, at the end of which time there should be cells started. I then take one frame with a little brood, and place it in a hive of drawn combs; set the colony off its bottom, and place the hive of drawn combs in its place, letting the queen run on to this one comb of brood. Over this I put a queen-excluder, and set the hive of brood on top, and put on the cover. The bees will finish the cells just as well as if the queen were caged for the ten days, and a new colony will be started below, so that, when the cells are nearly ripe, we can take the brood and bees from the upper story, and form nuclei without having to leave a single frame or any of the bees that are on them. If the colony was very strong there will soon be a good working colony on the old stand. By this method we are able to make one more nucleus from a colony than by the original Somerford plan. Any hive which we intend to use in this way we build up before caging the queen, so that there is a large amount of brood in every frame. I let the queen start about all the frames, and then set the fullest ones on the outside of the brood-nest, and in a short time have them all practically full of brood.

I make my nuclei by the Somerford plan, and sometimes stuff the entrances with grass, but oftener close them with a stick for three or four days. When I open them I push the stick so as to let only one or two bees pass at once for a couple of days, then open two inches. I have had brood in seven frames within fourteen days from making the divisions, and the bees storing in extracting combs in thirty days.

Last season I tried the Alexander method of

increase during apple-blossom, and instead of the queen making a start toward a brood-nest below the excluder, the bees jammed the lower story full of honey before there was a patch of brood as large as my hand. They refused to carry it above after I gave them extracting-supers, and, after a little, swarmed. I think it would have worked all right on a slow honey-flow, but I shall not try it again during apple-blossom time.

Marion, N. Y.

#### D. E. MERRILL, OF THE W. T. FALCONER MFG. CO., JAMESTOWN, N. Y.

BY E. R. ROOT.

As announced in our last issue, Mr. D. E. Merrill died on the 16th of May after lingering between life and death for six days following a paralytic stroke that he received at Bemus Point, on Lake Chautauqua, whither he had gone with some friends.

D. E. MERRILL.

Mr. Merrill had not been in good health for five or six years. Two years ago he received a slight stroke of paralysis, but apparently recovered. A couple of weeks ago with a party of friends he went up the lake, stopping at the place mentioned above. While at dinner, and without any warning, the fatal stroke came.

Mr. Merrill was 49 years of age, and leaves a wife and three children. He was prominent in Masonic circles, being a 32-degree member, and a member of the Royal Arcanum. In a social way he was connected with various clubs, and in

a business way was the junior partner of W. T. Falconer, of the W. T. Falconer Mfg. Co., so well known to our readers.

He started in business originally as a clerk in a wholesale grocery, and later was appointed paymaster in the United States Navy, finally entering the Signal Service. After this he was a book-keeper in a number of large institutions. In 1882 he started the manufacture of the Empire washing-machine, on which he obtained several patents. A little later he entered into partnership with W. T. Falconer, forming what is now known as the W. T. Falconer Mfg. Co. The washing-machine business appears to have been taken over, and later on the company went into the manufacture of advertising novelties, including rules, thermometers, and other specialties of a like nature, the making of bee-supplies being continued as before.

It is almost needless to say that the manufacturing business of the W. T. Falconer Mfg. Co. will go on as before.

## WHAT A 17-YEAR-OLD BOY CAN DO.

### Wiring Frames Without Piercing the End-bars.

BY WM. M. HASSLER.

The two boys shown in the engraving are my brothers, who are very much interested in bees, especially the younger one, who is eleven years old.

I commenced keeping bees myself four years ago with one box hive, when I was 17 years old. I now have 15 colonies in Danzenbaker hives, with 11-inch telescope covers. I winter them on the summer stands, and have always had good success. I make a brick of hard candy for each hive, and put it over the frames (*à la* Abbott), and I believe it is a good thing. From nine colonies, spring count, I produced nearly 500 lbs. of comb and extracted honey; but most of it was No. 1 and fancy comb in 4×5 sections. I think

most of the honey was from smartweed, which grew in abundance after the hailstorm which swept this part of the country and ruined the crops.

How can I prevent bees from gnawing the fences? What do you think of this way of wir-

THE HASSLER BROTHERS, OF PRINCETON, ILLS.

ing frames? Drive two nails, about 1½ inches long, in each end-bar; bend them into hooks, and wire, as shown in the diagram.

Princeton, Ill., Feb. 17.

[If your fences are made with the proper-sized bee-spaces, and the bees persist in gnawing the slats, it would be best to supersede the queen. It is not often that the bees give much trouble in this way unless the slats are too close together.

In the end your method of wiring the frames will not prove to be very satisfactory. The foundation at the point where the wires cross is held rigidly; and since there is nothing to prevent the upper half from sagging, buckling is quite often the result. This plan, known as the Keeny, has been used for years, and, so far as we know, has been generally abandoned.—ED.]

## ASPINWALL SLATTED FRAMES.

Using them with Langstroth and Hoffman Brood-combs, to Prevent Swarming, not Likely to Prove Successful; Closed-end Frames in a Box vs. Closed-end Frames in a Rack or Frame.

BY L. A. ASPINWALL.

[In order that our readers may better understand the points brought out by the inventor (Mr. Aspinwall, of the Aspinwall non-swarming hive with its slatted dummy frames), the reader is referred to the illustrations which we used in our issue for Nov. 15th, 1907, pages 1441, 1442, and 1443, of this hive. We will explain that we wrote Mr. Aspinwall that several were writing us, asking why those slatted dummies without the bee-space end-bars could not be used in an ordinary Langstroth brood-nest, one dummy alternating with every other brood-comb, increasing the capacity by adding extra stores. Mr. Aspinwall answers this in the subjoined article.—ED.]

Many have asked why the Aspinwall slatted frames could not be used in connection with standard Langstroth and Hoffman frames, and thus make a non-swarming hive. Apparently, at first thought, the saving would be an advantage

in that only a larger hive-body would be required, or two regular stories with slatted frames alternating the combs instead of one story and no slatted frames. If, however, estimates be made covering the cost of material for a large closed hive-body and an Aspinwall open rack or frame, I believe a balance would be found in favor of the latter. Taking into consideration the width of material used in each, we shall find narrow and small pieces of lumber used almost exclusively in the Aspinwall hive.

Furthermore, while some have expressed an opinion preferring solid or closed sides, there are two reasons why the frames should be supported with the least closure possible. This applies to closed-end frames, and prevents propolizing the outer sides of the uprights or ends. Closed-end frames surrounded by a bee-space, as contained in a solid casing or hive-body, have two objections which can not be overcome—the propolizing, which renders them difficult to separate, and the bee-space filled with bees, which interferes with rapid manipulation of the frames. This last objection also applies to ordinary hanging frames.

Without exaggeration, I believe that Aspinwall frames can be handled at least three times faster than any other style or make, which would be impossible unless contained in a rack to hold the comb-frames, thus avoiding the propolis and bees which would otherwise interfere.

A still more important feature is the prevention of an excessively high temperature during the oppressive heat of summer. But some one will raise a question as to the effect of cool nights. Upon examination we will find all colonies in closed bodies employing an excessively large force of workers both night and day in the work of ventilation. With Aspinwall hives but a small force is requisite during the day, while at night we hear but little more than the hum of contentment, unless the weather be exceptionally warm. Inasmuch as heat is one factor which induces swarming, its control must constitute a part of the non-swarmers. After having experimented with these hives so many years, I can not but realize the great disadvantage bees are compelled to labor under in ordinary hives, both in respect to overcoming the heat of summer and the crowded condition; yet many are trying to control swarming when the principal factor which induces swarming (a crowded hive) is not taken into consideration.

Let us now consider the relation of the cluster in reference to a thoroughly ventilated hive as contrasted with one having little or no provision for the comfort of the colony in this respect. Upon the technical observance of this feature in hive construction—namely, open hive-bodies and brood-frames with slatted ends, used in combination, we practically obtain a square, which, aside from the spherical, most economically conserves the warmth of the colony when separated by slatted frames. The writer can not forget the years of failure by attempting to use them with those of Langstroth length. So subtle are the combined forces which constitute successful inventions, we can not afford to overlook even those of the least importance; and in proportion as we follow the unerring laws of nature in this respect do we obtain success.

Having combined brood-frames with slatted ends for ventilation and distribution of the bees, also slatted frames alternating them, we obtain a uniform distribution of both bees and temperature laterally throughout the hive.

By adding a super we approximate a cubical form, which is also in accordance with the diffusion of warmth, and by tiering we practically obtain a cube, which, for conserving the warmth of the colony in the storage of honey, can not be equaled. The generating of heat in the lower story or brood-apartment of the hive and its ascendency through wide passageways afforded by the slatted frames, is a feature which will preclude the use of two stories of ordinary hive-bodies and slatted frames. The ordinary Langstroth or Hoffman frames are too short to afford ample supering surface—five square sections in a holder being requisite to the best results and to avoid excessive tiering.

Bee-keepers are cognizant of the fact that deep frames are not well adapted to storage of comb honey, much less two hive-bodies with slatted frames separating the combs and reducing the crowded condition of the colony. With such an arrangement, filling the brood-combs of the upper hive-body with honey in lieu of continued brood-rearing would be a natural result, especially as the queen is not likely to pass from a lower to an upper story unless by pressure of a crowded hive.

One valuable feature of the Aspinwall hive is the absolute freedom from brood in the supers, although no queen-excluding zinc is used. In hive construction the cost of frames is regarded as a small item; so that, in utilizing those of various makes to obtain a non-swarmers, no saving would result, as all parts required, aside from the frames, must be new. Inasmuch as the present style of hive-bodies made sufficiently large for a non-swarmers would cost as much as or more than the Aspinwall, there would be nothing utilized but twenty-five or thirty cents' worth of frames poorly adapted to the making of a non-swarmers.

In view of the numerous difficulties which must be surmounted in perfecting an invention, it behooves us to retain every feature which is requisite to perfect success. Therefore, let us transfer good clean combs from the Langstroth and Hoffman frames to those provided with slatted ends. These improved frames can be handled with great ease and rapidity, which is essential in this age of high-tension bee-keeping.

Jackson, Mich.

## EQUIPMENT FOR EXTRACTING HONEY.

### The McIntyre Uncapping-box; the Arrangement of the Furniture in the Honey-house.

BY E. D. TOWNSEND.

At our honey-houses at the extracting-yards we have a four-frame automatic extractor, a McIntyre uncapping-box, a honey-tank provided with a strainer and a gate at the bottom, and platform scales with an electric bell attached to give warning when a can is full. Since we put in cans all

of our honey as fast as it is extracted, we have on hand also a stock of 60-pound cans. Minor tools are necessary, such as uncapping-knives, pails, wash-dishes, towels, etc.

Our extractors are the automatic four-frame machines, none older than the 1907 model. We disposed of all our small extractors, and also of the old four-frame Cowan machines, for we wished to have nothing but the most up-to-date tools to work with.

Our McIntyre uncapping-box is made of galvanized steel, and is 4 ft. long, 2 ft. high, 2 ft. wide, as shown in the engraving. The slatted framework at the bottom is made a little smaller than the can so that it may be easily removed to be washed. As there is only a 1½-inch space under this frame for honey storage, we leave the gate open all the time so that nearly all of the room in the tank is available for the storage of cappings, as it should be.

The engraving does not show the frame at the top correctly, for the long side-pieces should be close enough together so that the frames can hang between them as though they were in the hives. After the honey is extracted, the combs may be placed back in this rack; but the principal value of the arrangement consists in providing a place where the *uncapped* combs may be hung to drip before they are extracted, for in this way no extra apparatus is needed.

The two short pieces of the framework at the top should be nailed on the bottom of the long side-pieces about 1¼ inches from either end. It can be seen that, when the long side-pieces rest on top of the tank, the short cross-pieces fit just inside, keeping the framework from sliding either way, and yet allowing it to be easily removed

when the cappings are taken out. The metal pieces containing nail-points can be tacked on in any position to suit the convenience of the operator.

We have used many different designs of uncapping-boxes, but none seem to me quite so convenient as this McIntyre box. It will hold all of the cappings from one extracting in a yard of ordinary size. We use a six-tined short-handled fork for handling the cappings, and each morning the dry cappings from the day before are pitched up toward one end of the tank, and in this way the honey from the new cappings does not have to drain through the dry ones over and over again as it would if we were to uncap on top of the cappings left from the day before. In one instance we had more cappings than we could keep in the tank, and a sugar-barrel with a perforated bottom was set over a galvanized steel washtub, and the dry cappings pitched into it. In this way the capacity of the tank may be said to be unlimited. The advantage of the large area of the bottom is that the honey drains out of the cappings much better if they are spread out in a thin layer than it could in a deep tank where the bottom is comparatively small.

The cost of the tank alone is about \$4.00, the freight making it perhaps \$5.00. We use the Perfection 1½-inch gate, which costs 75 cts. If the woodwork should cost \$2.00, the entire expense of the tank complete would be about \$7.75, and we think we have a much better and cheaper arrangement than a wooden box.

The honey as it comes from the extractor is drawn off into a 14-quart pail. We never make the mistake of leaving the extractor-gate open all of the time, for it is too easy to forget and allow the pail to run over, making a big mess on the floor. In order to avoid this waste of honey we at one time went to the expense of having shallow pans made to catch the overflow in case we forgot. We now allow the pail to remain inverted over the strainer until the reel of the extractor begins to "swim" in the honey in the bottom of the extractor. We then draw off a pail of honey without letting go of the gate; for when the honey is warm it does not take one-fourth of a minute to fill the pail through the large gate, and there is no risk of running the pail over. There is also the advantage that the pail may be draining during the time when another pailful is being extracted.

The strainer tank is of galvanized steel, and holds 15 or 20 gallons of honey. A heavy wire selvage is put around the top to stiffen it; and as this wire is on the outside it is easy to fasten on the cheese-cloth strainer,

FIG. 1.—THE MCINTYRE UNCAPPING-BOX AS USED BY E. D. TOWNSEND.

which is held in place with a small rope drawn tight by being twisted with a stick. This cloth strainer must, of course, be fastened very firmly or it will go down into the can when a pail of honey is emptied on to it. At the bottom of the strainer-tank is a 1½-inch Perfection gate through which the honey always runs in a round stream which is just right for filling the 60-pound screw-cap cans. Most of the other gates throw the stream to one side during the time they are being opened or closed, and some of the honey is, therefore, daubed over the side of the can. All this is avoided by using the Perfection gate, which throws a round stream, no matter how wide it is opened.

The strainer-can is elevated in order to run the honey from the gate into a 60-pound can set on the scales. The gate is open all the time except when the cans are changed. An electrical alarm, as first described by Mr. Hutchinson, is used to give us warning when the can is full—see Fig. 2. No one should hesitate about trying one of these alarms, for they are very simple. The engraving shows the method of connecting the bell to the battery. In brief, two wires run from the two posts on the battery to the two posts on the bell; but one wire is broken, one of the ends being fastened to the scale-beam at the pivot, and the other being located just above the outside end of the beam. It can be seen that, when the can is full, the scale-beam rises and the circuit is completed so that the bell rings. It is necessary to have all of the connections tight, as the bell may fail to ring if there are any loose contacts. We set the scales as usual at the 62½-pound mark to allow for the 60 pounds of honey and the weight of the can, and then lay a two-pound weight on top of the can and turn on the honey and go on with our work. It can be seen that, when the scale-beam goes up and rings the bell, there will be 58 pounds of honey in the can. We then remove the weight and weigh the honey as usual.

Mr. E. E. Coveyou, of Petoskey, Mich., has made an automatic scale that closes the gate when the can is full. He uses an eight-frame automatic extractor provided with a Holtermann strainer in the bottom. This extractor is located on the platform about 2 ft. above the honey-house floor, and a rubber hose from the strainer in the extractor conveys the honey to the gate on the scales. This rubber hose stops all the vibrations

FIG. 2.—E. D. TOWNSEND'S ARRANGEMENT OF STRAINER AND SCALES, ILLUSTRATING THE HUTCHINSON AUTOMATIC ALARM.

caused by the running of the extractor, and this precaution is really necessary; for if the automatic scales were fastened solid with the extractor the vibration would so affect the flow of honey that some of it would not go into the small openings in the 60-pound cans.

Remus, Mich.

[Mr. Hutchinson will soon describe the Coveyou automatic scale in these columns.—Ed.]

## THE TROUBLES OF AN AMATEUR BEE-KEEPER.

### Failure through Success.

BY F. DUNDAS TODD.

Bees not troublesome? May be not; but you could not prove the fact on the witness-stand by me. My neighbors learned of my trouble, and came to give me sympathy, but I did not want it. I told them I was delighted with things as they were. I really was, but they could not understand. I had a problem to solve, which was something far more fascinating than robbing a hive of fifty pounds of honey at the end of a smooth-flowing season. So I begged to be left alone with my entrancing troubles, and turned more assiduously than ever to the books. I bought

all I came across, subscribed for three magazines, and put all my spare minutes on the ever growing problem of bees.

Then I bought another hive, being determined to have a first-class one as a standard of comparison. It came from Flint, and I know now that Mr. Hutchinson sent me a dandy. I wondered how so many bees could find room in so little space.

My first went from bad to worse, and at last a happy idea struck me. The wonder is, it did not strike me before. As editor of a technical journal I had to answer daily over a dozen letters from people who were in trouble, and so I decided to call on Mr. York and state my case for his opinion. He was kindness itself, and at the outset doubted my diagnosis of bee paralysis. Nay, more; he volunteered to examine the hive, diagnose the disease, and prescribe the remedy. He made short work by pronouncing it a case of queenlessness, with at least one laying worker. Remedy, total extinction. I pictured the sulphur-chamber; but, no; he advised placing it above my other hive with a sheet of ordinary newspaper between, in the center of which was punched a small hole with an ordinary leadpencil as the readiest tool to be found. He went even further, and administered the medicine himself.

A rather amusing incident then happened—in fact, two of them. Mr. York looked over my new hive to see how it had stood the journey, and of course I wanted to see the queen, as I had never seen one. I remember he declined to put on gloves. I had had too sharp an experience with my first effort to be ever without them; in fact, the bees got at my fingers through the cotton lots of times until I oiled the part that covered my hands. That oiling experience was amusing because I soaked them so thoroughly that it took two weeks' exposure over a steam-boiler to dry them. The next time I applied sweet oil to bee-gloves I tried to see how little I could lay on them; but even that was a plenty. So I closely watched Mr. York's fingers as he handled the frames, and I must admit I chuckled when a sudden "ouch" broke from his lips as he sharply swung his left hand against his trowsers leg. It is not the same word I would have used, but I guess it meant about the same thing.

To return to the queen-hunt. The first over-haul was fruitless; the second, the same. Mr. York decided the task was hopeless, and made all preparations to close the hive. I happened to step behind him and look downward, when my eye caught sight of a large yellow bee just above the calf of his leg. I quietly mentioned the fact to him, so he gently looked round and pronounced that I had found the queen, which he speedily returned to the frames, in which she disappeared. My acquaintanceship with Mr. York had been very short, but I had at one time lived several years in his "locality," and knew that he bore a very excellent reputation, so did not insist that he was trying leg-bail tricks with my only queen.

In less than a week my double and now only hive had a lot of finely chewed paper lying around its entrance; and when the upper hive was lifted I found the paper entirely gone, and evidence that the bees from the lower half had taken full possession. A few weeks more this hive was simply full of bees; and since white clover came in bloom

I decided to dodge swarming by dividing my hive. I had never in my life seen a swarm of bees, and I never wanted to. My friend who had kept bees as a boy had suffered a relapse of bee-fever, and bought a hive from Mr. Hutchinson when I got my second. Being a practical man he despised books, and told me I was simply wasting time, as the only way to learn bee-keeping was by experience. Then the theorist got on his nerve and proposed a competition, the test to be selected by the practical man. He said honey, and honey it would be.

So to the books and magazines I went more assiduously than ever. I had one Dovetailed and one Danzenbaker hive, so I had to decide which I would adopt, and I studied the pros and cons. The decision was in favor of the latter on purely theoretical grounds, and so two more were got. I ordered a couple of queens, and on their arrival I drew ten frames from my double-decker and placed five in each, alternating with empty frames, then introduced the queens, which were accepted. Transferring seemed a big problem, but it had to be done if uniformity of appliances were to be secured, so this was tackled and successfully accomplished.

The season of 1906 in Illinois was a poor one, as every one knows, and I waited expectantly long weeks to see what a honey-flow looked like. White clover bloomed June 1, but the bees did not develop that tremendous energy I had read about but had never seen. My practical friend was longing for a swarm, and in picturesque language he described the delirium of the bees as they rushed pellmell out into the wide, wide world to seek a new home. To him at that moment the whole pleasure of bee-keeping seemed to consist of one huge swarm of absconding bees, with him racing after them in wild pursuit. I am too lazy for that kind of excitement, and prefer expansion under control.

Sweet clover bloomed July 1, and by the middle of the month I was able to provide a lawn party of a dozen at my house with six complete sections, purity guaranteed, and believed, since they saw the honey taken from the super.

August 15 the honey-flow was over, and my first venture in bee-keeping stood thus: 30 fine sections of honey from hive No. 1; one new hive had finished its combs and built up in good shape; another new one, in fair shape, but not nearly so good as the other.

My friendly rival had all the fun he wanted racing after three swarms, climbing as many trees, and learning by experience that what was fun at fifteen is a nuisance at forty-five. But he got no honey. Need I say how I would occasionally call him up on the phone, and in my blandest tones tell him I had a rather curious substance called honey at my house; and, if he cared to see it, just to come over. Or I would ask him very politely if anybody had ever told him what bees were kept for; if he did not know I could tell him—it was to get honey. Twice I sent a section to his wife, with my compliments, and he handed me the cigars when we met.

The theorist had beaten the practical man. The Danzenbaker hive had won a victory over the Dovetailed.

Medford, Oregon.

*To be continued.*

## HEADS OF GRAIN FROM DIFFERENT FIELDS

HERSHISHER'S SCHEME OF SPRING MANAGEMENT IN-DORSED; THE EGG-LAYING POWER OF A QUEEN THAT HAS BEEN CONFINED IN A WEAK NUCLEUS.

After reading the article by Mr. Hershiser on page 347, I wish I could get every bee-keeper to read it twice. If any one is in doubt about a fresh queen being able to lay all the eggs an average colony can take care of, let him try a queen that has been held in check by a weak colony until about fruit-bloom time, and then give her all the conditions favorable to brood-rearing, and notice the results. I doubt if they will think it necessary to have two queens to the hive.

It is not so much the queen that gives results as the conditions by which she is surrounded; yet there is a vast difference in favor of a fresh queen as compared with one that has, as it were, laid out her litter and is approaching the time of her usual summer vacation.

Giving eggs and young brood to a strong colony will retard swarming, even if you do not take any of their mature brood from them; yet there is nothing that will boom brood-rearing in a weak colony like giving them a frame of hatching brood; but if you want to go them one better, give at the same time one of the combs just outside the brood-nest in the strong colony that contains no eggs, but is filled with raw nectar and newly gathered pollen. This, of course, is to be placed next to the brood in the weak colony, never between the combs of brood.

So. Cabot, Vt.

D. S. HALL.

### DIFFERENT SHAPES AND SIZES OF FOUNDATION STARTERS.

I was much interested in Mr. W. A. Pryal's article in the Dec. 15th issue, on the subject of bottom starters, as I have been experimenting with them somewhat the past season. I had about the same luck with them that he did, except in one colony which I experimented on by putting foundation in the sections in several different ways—top starter, full sheet, top and bottom starters. There were even a few in which I did not put foundation. The sections were all filled up full, and you could scarcely tell one section from another. In fact, the honey would grade No. 1. The bees in this particular colony are the best to work in sections of any that I have ever had, and they did not offer to swarm at all the past season. The queen of this colony is a daughter of an untested red-clover queen. The bees are as gentle to handle as any one could wish.

EDW. A. REDDOUT.

Baldwinsville, N. Y.

### SOME OF THE IMPORTANT POLLEN AND HONEY PRODUCING PLANTS OF THE CANADIAN NORTHWEST.

The first bloom we have here in the spring is from the pussy-willow. It grows very plentifully along rivers and creeks in the Canadian Northwest, and is a great pollen-producer. At about the same time we have the box-elder, or ash-leav-

ed maple, and the prairie crocus, both important for pollen. A little later the wild cherries, currants, and wild roses come in bloom, and still later, about the beginning of July, the willow-herb and wild vetch come. Much honey is obtained from the willow-herb, or fireweed. Last of all come the wild aster and the goldenrod. A considerable amount of honey is taken from goldenrod some years. All these grow in the wooded districts except the crocus.

Swarthmore, Sask.

EDWIN J. HOPE.

### MEETING OF PENNSYLVANIA BEE-KEEPERS.

The Lebanon Bee-keepers' Association held its regular spring meeting at the apiary of Messrs. H. K. Beard & Brother, near White Oak Station, on Saturday afternoon, May 2. President Miller, of Myerstown, occupied the chair. About seventy-five bee-keepers were present, and all enjoyed the different addresses and took part in asking and answering questions.

The question-box was a feature of the meeting, and there were all sorts of questions, interesting and instructive. Many different views and methods were thus brought to light. This will also be a feature of the July meeting, and all bee-keepers who want questions answered should make it a point to have them in the hands of the secretary by July 1, so as to give ample time to procure speakers who will answer them intelligently.

C. F. KLEES, Sec.

Anville, Pa.

### NEW STYLE OF MILLER INTRODUCING-CAGE.

I am sending you a style of Miller introducing-cage upon which I should like to have your opinion. You will notice the plug can be inserted either way. One way covers the candy so that

neither bees nor queen can gain access to it, while the other way leaves it free for the bees to work on.

CHAS. G. MACKLIN.

Morrison, Ill.

[There are some features about this cage that are very good; but if the cage is made small enough to go down between the combs the hole in the block will be very small—probably too small for the queen to pass through safely with-

out danger of being stuck fast by the candy adhering to the inner wall of the hole.—Ed.]

#### A SWARM-CATCHER MADE OF A BURLAP SACK.

Take a good strong iron barrel-hoop. Sew a good fertilizer-sack to the hoop, then squeeze the latter to an oval shape; put in a handle, any

length you wish. When you shake the bees in, give half a turn. That closes the sack, and not a bee can escape; then dump in front of the hive. Tontogany, Ohio. R. L. McCOLLEY.

[The same general plan of a swarm-catching sack was shown in the earlier editions of our *A B C of Bee Culture*, and, in fact, is still shown there. See page 410 of the last edition. The device is so simple that any one can make it.—Ed.]

#### BEEES AND HONEY IN UTAH.

I started in last spring with five hives. From these I captured seven swarms. One of the five, and also one of the swarms, failed to make even a pound of surplus, on account of foul brood; but from the other four and their swarm I got 924 lbs. of nice comb honey, the most being made, by swarm No. 7, which was cast May 27, which made 177 lbs. The next best was 151 by swarm No. 8. One of the original five swarmed four times; and at the end of the season I had 113 lbs. of surplus to its credit. I called it my crazy hive, but there seemed to be "method in its madness," after all.

Last Sunday, as Mrs. Tidd and I were returning from the Easter service at Provo, we drove right up into a mammoth swarm of bees as we reached the house. We were not looking for a swarm quite so early in the season, but had hives ready in the event any should come. They settled on the ground in our little pasture at the roots of some cherry-sprouts. I soon had a hive there, but was having some trouble getting them started to go in when Mrs. Tidd said, "Why, there is *another* swarm."

I looked, and there, about two rods away, on a weed about a foot high, was another cluster. As my bees were all leaving, and clustering there too, I concluded that the queen must be there, and so I moved the hive over to Mrs. Tidd's

cluster, and soon had them hived nicely, and saw the queen as she went in. I want to say right here that Mrs. Tidd is a great help to me in the apiary, and the outdoor exercise is excellent for her.

I bought a few more stands this spring, and now have 16 including the Easter swarm. It is doing beautifully so far. Fruit-trees are all in bloom now.

C. H. TIDD.

Provo, Utah, April 22.

P. S.—Our Homes department, conducted by you, deserves special mention, and I hope you may be abundantly successful in your work of reformation.

#### THE DEWEY FOUNDATION-FASTENING MACHINE.

There are now on the market a number of devices for fastening starters, employing a hot-plate; but while all have their merits the principle of the flat plate is subject to serious objection. My device is a coverless box with a sliding table. The chain is secured to a small lever clip which forces the moving table forward when pressure is applied to the treadle. As the table slides forward or away from the operator the curved plate swings forward toward the operator. The section is held in position by the curved spring. As the machine is closed the heater-plate describes an arc, passing over and into the section, and coming to rest just below the stationary plate. It is this position of the hot plate that makes this device so distinctive. It does not touch the section at any point. Neither does it come in contact with any part of the machine adjacent to the section, but is suspended free from any thing that could be soiled. When the section has been adjusted and the machine closed, the starter is slid down the small plate until it touches the hot plate; the pressure on the treadle is then released; and as the hot plate recedes from

the section the starter is pushed down until it touches the section, to which it is securely and centrally fastened. All dripping wax is carried away from the section to the rear of the hot plate, and may be collected in a dish placed at the rear if desired.

Starters are fastened so securely that the wax will tear before they will start from the section. Full sheets or  $\frac{1}{4}$ -inch starters are fastened with equal ease. Many have reported a speed of 500 starters per hour, and 600 per hour has been reported.

Aside from its many other desirable features, no soot can soil the section or dripping wax clog the machine. The small kerosene-oil lamp, using a no-chimney burner, produces an intensely hot flame with nearly complete combustion.

Great Barrington, Mass. D. H. DEWEY.

## OUR HOMES

By A. I. Root

Give, and it shall be given unto you; good measure, pressed down and shaken together, and running over, shall men give into your bosom. For with the same measure that ye mete withal, it shall be measured to you again.—LUKE 6:38.

Great peace have they which love thy law, and nothing shall offend them.—PSALM 119:165.

Dear friends, I have used the above texts several times, especially the first one, and it pains me to find out that a good many do not take it as I meant it. This is especially the case when I recently spoke of the labor troubles, and declared that the gospel of Jesus Christ would be a perfect and unerring remedy. Of course, I meant that this gospel should apply to the wealthy employer as well as to the day laborer—in fact, to all humanity, high and low, rich and poor, white and black. May the Holy Spirit guide me, and so direct me that I shall be able this June morning to make my meaning plain.

Many good people seem to be *afraid* to be liberal and generous, and I fear that some of us are, at least at times, afraid to be *honest*. A good friend of mine (and a *money-lender*) used to say, many years ago, that when a man does all he *agrees* to do he is a pretty good man, and that is true. Oh what a blessing it would be if all the people we meet were always ready and willing to do *all* they agree—our transportation companies, for instance, and particularly our express companies. I once expressed a part of a bicycle from Cleveland to Chicago. I paid the charges in advance, and got a receipt saying, "Paid through to destination." But when I called at the express office in Chicago there was something more to pay. I produced my receipt, and told the clerk that I had it in black and white, paid through to destination. "I do not care any thing about your receipt," he said, "nor what you paid in Cleveland. You can not have this property unless you pay these charges." As the amount was small I did not quarrel about it; but, even though I am a man of peace I have since felt sorry I did not take the matter up with the company and make them fix it—not because of the amount of money involved, but because of the principle and the precedent it helped to establish. But I am not going to talk about express companies just now.

Some years ago in the poultry department in this journal there was an advertisement that did not look just right. I investigated, and found it came from the editor of a poultry journal published in ———, Ohio. Now, notwithstanding he was the editor and proprietor of a *poultry journal*, he was trying to sell a recipe for preserving eggs for several dollars, and that, too, to his subscribers. Let us look at it a minute. We have periodicals and journals representing almost every industry nowadays. The proprietors are leaving no stones unturned to get people to subscribe; and, whether they say so or not in plain black and white, they are supposed to be giving their readers promptly, each month, every new discovery or invention that will be of value to the poultry-keeper. In fact, that is the mission of every class journal.

Well, now, this man in his circular for pre-

serving eggs *admits* that he has some valuable secrets that he is holding back from his readers. If you will just send him the "dollars" he is begging for he will let you "into" *something wonderful*. I am sorry I did not save the circular; but if it did not say it would preserve the eggs so perfectly for a whole year that they would then hatch out good chickens, it came pretty near it. We refused to give his advertisement another insertion, and dropped the matter there.

For years this business of selling recipes for preserving eggs has been going on. We get a circular every few days, even yet, although our experiment stations have again and again explained the whole matter, and the Department at Washington has sent out a bulletin giving all the information obtainable in regard to it from an unbiased source. I might say briefly that the soluble glass seems to be equal if not superior to any thing known.

Just now all or nearly all of our poultry journals give place to advertising secrets. The Hogan system and the Potter system are still offered for from one to ten dollars, and the editor of one poultry journal defends the business of advertising secrets, and ends up by saying it is everybody's privilege to let them alone if they do not want them. Some of our foreign journals editorially *advise* their readers to pay ten dollars for the Hogan secret. Now, the editor of any industrial journal can, if he has energy and enterprise, get hold of all information of this kind, and do it, too, in an honest and gentlemanly way. If he chooses he can *buy* the secret and give it to his readers free, or he can get the experiment stations throughout our land to assist him in giving people every thing that is of value to them. Our different experiment stations have as a unit declared over and over again that nothing of value is *ever* peddled out in the way of secrets. Let me give you an illustration. Suppose your neighbor's potatoes are being eaten up by potato-bugs, and that his patch will be ruined before night. We will suppose he is new in the business, and does not know what to do nor how to do it; and suppose you have just bought the secret, for which you paid one or even five dollars, as the case may be; but when he comes to you in his distress you tell him, "I would let you have my recipe, friend A., in a minute; but I have signed a contract not to divulge nor to let anybody 'look into the book' containing the directions. if it were not for that contract, with my name to it in black and white, I would help you out of your trouble straightway; but as it is, I do not see but you will have to let your potatoes all go. You see I am tied up and helpless."

May be I have put the above a little too strongly, but I think not. I once remonstrated with a young physician because he refused to tell his patients what the medicine was he was giving them. He turned on me with scorn, saying something as follows:

"Do you think I am going to give away my secrets that I have learned by long study and much experience? Not much! Shall I tell the people what I use to cure them so they can go to the drugstore and buy their own medicine without consulting me? Not if I know it."

I have never heard of that young doctor since. In fact, I doubt if he *is* a doctor at all by this

time. When I call a physician I always tell him plainly at the outset that I very much prefer to have advice rather than medicine—that is, if no medicine is *really* needed; and when he tells me it is something I need not be at all worried about I sometimes have to urge him to take pay simply for giving me the benefit of his advice and experience.

Now, in every thing I have to say, dear friends, please remember that I may be mistaken and in the wrong. Please keep in mind that I am simply making suggestions to you and giving you *my* point of view and observation. Now, when I give you a little of my experience of years past, please do not think I am boasting. It is the Lord Jesus Christ I want to hold up and not poor faulty A. I. Root. When I began reading my Bible, something over thirty years ago, I turned right square about in a good many things; and that beautiful text, "Give, and it shall be given unto you," helped me greatly in turning right square about. I had at that time no patent on my all-metal honey-extractor; and my impression is now that if nine-tenths of all the patents had never been taken out or granted, the world would be just as well off. I have no doubt our older readers will remember that when GLEANINGS was started I commenced ransacking the face of the whole earth, if you will excuse the expression, in order to get hold of every thing that was valuable to bee-keepers; and then I sat up nights (and set type myself at times) to get these valuable facts before our readers just as soon as possible. When I had worked out a better plan for sending queens by mail I sent a special circular free of charge to all the friends who were mailing queens. If anybody advertised any *secrets* in bee-keeping, making artificial honey, etc., I sent the money and gave you the secret free of charge.

There is another text along the same line from the same chapter from which my first one comes. It says, "Do good and lend, hoping for nothing again; and your reward shall be great, and ye shall be called the children of the Highest." Why, is not that promise just glorious? I never fully realized it until *just this minute* as my eye alighted on it in the open Bible that lies before me as I dictate. Jesus not only says our reward shall be great but that we shall be the children of the Highest—*God's* children.

Well, if I am correct I made the first all-metal honey-extractor, toward forty years ago. I told you all about it in the old *American Bee Journal*. Although I might have patented several features of it, I took out no patents. Just about this time some visitors from Toledo, O., came to see us. One of them asked a good many questions about my new extractor; and he even took out his rule and made measurements of different parts of it and put it down in a notebook. I supposed he was thinking of making one for his own use, and said nothing about it, and thought but little about it until a few weeks later, when an advertisement appeared in the *American Bee Journal* that read something as follows:

"Honey-extractors made just like A. I. Root's, but \$1.00 cheaper than the Root extractors."

Of course, I felt a little hurt at this, but concluded to say nothing. A little later my good friend Prof. Cook got out his first edition of the *Bee-keepers' Manual*, and I felt still more hurt

to see that he had pictured *this* extractor (copied from mine) with the manufacturer's name on the printed picture. I did not lower my price on account of the advertisement; but I tried hard to make a *better* machine than I had been making for the same money. Some of the veterans will remember this first frail machine, and the amount of work it did was really remarkable at that stage of proceedings.

Now, friends, we are about ready for the second text. I first got hold of it at a union revival meeting here in Medina. Somebody got up in meeting and said in a voice that startled us all, "Great peace have they that love thy law, and nothing shall offend them." Whenever I feel hurt I try to remember about the "great peace"—that it is your privilege and mine to have it; and then I try again not to be *offended*, no matter what may happen or come up. Oh what a bright and happy world this would be if people would not take *offense* too easily! When we get to the stage (or *age*) where we shall not take offense, no matter what shall happen, we are getting pretty close to heaven.

Some time ago I criticised somewhat the *Woman's National Daily*; but now it is getting to be not only right on the side of the *temperance* war, but it gives me some happy surprises in regard to other things. In a recent issue there is an editorial headed "Revolverless Robbery." A trolley car in Philadelphia was held up and robbed, and the robbers went right through without hindrance because there was not a revolver in the whole crowd—not even in the hands of the conductor. The editor rejoices over this fact; and I want to add, "May God be praised that Philadelphia had at least *one* carload of people without a revolver." It is intimated that the robbers themselves did not even show a revolver; and Editor Lewis thinks it was a great deal better than to have a fusillade of bullets that would be more likely to injure innocent people than to kill the robbers, as happened in the following case, which I quote from the very same paper.

#### FIVE SHOT IN MAN-HUNT.

SERGEANT, KY., May 27.—Officers of the county have been on a man-hunt in the Blackberry Creek region near here. Their special object was to capture Sam and Thomas Followay, wanted for lawlessness, and believed to be trying to escape across the Virginia line. In a Hungarian settlement where it was thought the two men were concealed, there was a general shooting-scraps, and five of the Hungarians were shot. Two of them were women, and their wounds are mortal.

It is the old story of Nimble Dick, who not only failed to hit the obnoxious crow but destroyed a valuable cat sitting in the window.\*

Well, while I give a hearty amen to that part of it, I *do* think the police of that great city should leave no stone unturned in order to get hold of those highwaymen. And let me suggest that the first and foremost "stone" to be rolled over would be to get rid of the saloons that curse not only Philadelphia but every other great city in our land.

\*As some of the children may never have heard about "Nimble Dick" I have asked our stenographer to give you a verse that sent my memory back fifty years or more as soon as he suggested the application of the moral to the shooting of five persons.

Nimble Dick, he was so quick  
He tumbled over a stick of timber;  
He bent his bow to shoot a crow,  
And killed a cat in the window.

I have just one other illustration to give you; and I have been thinking that perhaps I *may* be a little more out of the way than the good friend whom I am going to criticise just a little. When I heard that beautiful hymn for the first time in St. Louis, "The King's Business," I spoke of it in these Home papers, and I said the most I could remember of it was the closing words, "Be ye reconciled to God." Just as soon as that journal had gone out, somebody tore a leaf out of his hymn-book and mailed it to me, giving the words and music. I mentioned it in GLEANINGS, and promised to give our readers the words and hymn. After I got the electrolyte plate of it, however, Mr. Calvert called my attention to the fact that it was copyrighted, and that I could not print it in GLEANINGS, nor even have copies printed for use in mission Sunday-schools in Michigan and Florida and other places, without permission. I accordingly wrote to the owner of the copyright. I also inclosed some copies of other hymns, words only, that I had been using in Sunday-schools so the pupils and all could sing the new pieces as they came out, even if they did not have the books. Below is his reply:

Dear Mr. Root:—I am very glad indeed that you discovered that "The King's Business" was copyrighted, for under no conditions do I allow anybody to reproduce the hymn. It is too valuable a copyright; and, while you might think it would be a good advertisement to send free copies out, at the same time I prefer to advertise in another way, so you will please not distribute any copies of the song as per your reproduction.

Chicago, Ill., July 13, 1907.

E. O. EXCELL.

Of course, I felt a little hurt, but let the matter drop. Some time afterward, however, it occurred to me that friend Excell would probably have no objection to my using the *words* only without the music, and I wrote him, telling him I wanted to use the leaves to distribute to poor children who had no money to buy books. Below is his reply to that:

Dear Mr. Root:—I have yours of the 27th. Replying I will say I am not in the habit of allowing my copyrighted hymns to be printed words only. The fact is, it might vitiate the copyright, inasmuch as my songs are all copyrighted, words and music. You ought to be very careful in printing Sunday-school songs words only, for fear that you print some copyrighted hymns and thereby throw yourself liable. There is a fine of \$1.00 for each copy so printed. I am sorry I am not in a position to accommodate you this time.

Chicago, Ill., Aug. 30, 1907.

E. O. EXCELL.

Now, I shall have to confess that it seemed to me a little severe that a great Christian worker, whose fame extends all over the world, should object to letting these beautiful hymns revive and gladden the Sunday-schools of our land,\* but that other text, about "great peace" and not being "offended," brightened me up again. And then I remembered that friend Excell might have said, in defense of his course, that the very hymn I wanted, with a dozen others, including the celebrated "Glory Song," were published in pamphlet form for just the purpose I needed, at the exceedingly low price of \$2.00 a hundred; and that if these poor children could not afford two cents

\*When I was tempted to feel hurt at the position friend Excell takes, it looked to me something like this: The hymn supposes an ambassador has been sent from the King of kings—

"An ambassador to be

Of realms beyond the sea;"

and this ambassador has a message from the King; in fact, the chorus reads:

"This is the message that I bring—

A message angels fane would sing."

Well, this "message" the "ambassador" brings, I should have given you all had not brother Excell objected.

for a copy the superintendent and officers of the school could easily raise the sum needed.

It is my privilege, without question, to give my time and money and inventions to the world without charge; but I should certainly be out of place, and a very poor Christian, if I should say that *all* inventions should be given to the world without the protection of any patent. Friend Lewis says in that editorial I alluded to that the world would be very much better off without revolvers, or perhaps without so *many* revolvers. He says, "A few drinks and a ready revolver is a combination that has sent many a man and woman too to an untimely death, and many more to the gallows, and prisons for life, or for a long time."

Well, in looking back over the years, and especially in getting the Patent Office Reports, as we do regularly, I am forced to believe that not only could we get along with fewer *revolvers* but also with fewer *patents* and *patent rights*. The man who copied my extractor very soon stopped making honey-extractors, and for years nobody else went into the business—at least very much; for while I had no patents, my profits were so close there was not much temptation to try to "cut under" my prices. When foundation-rolls came out, there were half a dozen or more invented and as many patented; but although I never applied for any patent, I rested for security on making a machine at so low a price that nobody else would care to undertake it. In just a little while the trade gradually and peaceably settled down into our hands. We have had no trouble in litigation or in fighting rivals; and so with all or nearly all of our other improvements in bee-supplies; and over and over again, as the years have passed, have I seen money wasted in getting out patents, and perhaps more still wasted in fighting claims, when in a little time, had the owner of the invention waited, he would have seen something come up much better, or else found that the great busy world did not need his improvements, and that he would have been better off in dollars and cents, and still better off in having a good time in this world of ours had he followed that wonderful text, "Give, and it shall be given unto you;" and in a few years, or only a few months or weeks, he would have had reason to believe in the promise in the other part of the text, "Good measure, pressed down, shaken together, and running over."

A great part of the exhortation of our Lord and Master while here on earth was against selfishness. Over and over again he begged and entreated and *implored* humanity to forget self and to find happiness and enjoyment in laboring for the good of others. What a tremendous rebuke his pure and unselfish life is to the grafters of the present day! Just think of it, friends. We hunt the world over to find honest men—men who can be trusted with our public funds and our public business. Some good man, or one who is supposed to be so, is appointed as inspector of the fertilizers manufactured for the use of farmers. A great good has been accomplished along this line; but every little while some greedy manufacturer goes to this inspector and tries to buy him off; and they can afford to give him large sums of money if he will favor their particular brand, or persuade him to "look the other way"

while they are fleeing the farmers. When such a man is exposed he is put out of office, and perhaps sent to the penitentiary—that is, providing he and the manufacturers' back of him have not enough ill-gotten gains to get him off scot free. Now, these men who succeed in tricking the government and the people are not happy. The money they have stolen does not do them any good. When they are exposed, as you will notice by the papers, they often commit suicide; and I maintain that such a course is only "jumping out of the frying-pan into the fire." It may not be a *literal* fire, but I am persuaded it is something even *worse* than fire. Now, Jesus came from his home in heaven down to earth to bring us glad tidings—peace and happiness and enjoyment that God in his great mercy has provided for all of us; and he tells us to be liberal and to lend, hoping for nothing again. He tells to lay up treasure in heaven where it will not get away from us—to lay it where we can find it when we get to heaven. Naked and penniless we came into this world, and naked and penniless we shall go out of it. Oh! why do not men and women recognize that all this wealth and property and money that they are raking and scraping together may have to be given up in just a few hours?

I remember a friend who could not be happy; in fact, he could scarcely eat or sleep because he was likely to lose something like \$500 that *he* thought he ought to have, and some of his relatives did *not* think so; but after a lot of jangling and hard feeling he got the money. Did he buy something with it to make him happy? No, he just put it out at interest, and in a little while he died suddenly without ever having had any good at all from the \$500, and a great lot of money *besides*, that he had been spending his life's energies in piling up where it would bring in more.\* Do you know of such people? Now, my dear friends, let us come a little closer home. Are you sure *you* are not one of that sort? If so, suppose you get down your Testament and read that sixth chapter of Luke that I have quoted from, and see how many other passages there are (that contain the precious words of God's only Son) that read something like our text—"Give, and it shall be given unto you, good measure, pressed down, and shaken together."

---

## POULTRY DEPARTMENT

---

### HOW TO MAKE A HEN'S NEST.

Some of you may laugh at my title; in fact, I have heard there has been *considerable* laughing at my poultry talk, and *perhaps* at my poultry knowledge; and some people may wonder what there can be new about making hens' nests. Well, now, friends, there are a good many who do not know how to make a hen's nest, and I begin to think I belong in that crowd. In the last issue I spoke about sitting hens breaking their

eggs; but it did not occur to me that one great reason for sitting hens breaking their eggs is because they are not provided with proper nests. The eggs broken by sitting hens are costing this nation alone annually thousands of dollars; and if you will permit me to go so far as to "count chickens before they are hatched" (just this once, you know), I do not know but the loss will run up into the millions. I have been advocating giving the hens fifteen or twenty eggs; but a cousin of mine had a White Leghorn hen that stole her nest up in the hay-mow, and hatched *twenty-one* chickens all by herself. The chickens kept rattling down from the hay-mow until they thought there was no end to them. Well, now, this little hen successfully brought up the twenty-one chicks, and they were sold in the market at a good price. If a little White Leghorn hen can hatch twenty-one chickens, how many could a Light Brahma or some of the other big breeds hatch? You may suggest that these big breeds are the ones that break the eggs; but if I should be able to convince you that it is the fault of the *nest*, instead of the awkward and contrary hen, you would have to admit there is a great need—in fact, I might say, a "long-felt want" of a *better* hen's nest. Biddy breaks an egg, and in rolling them around, as she should do, about every egg in the nest gets more or less daubed, and this daubing cuts off the pure air from the baby chick. We are making a great ado about pure air nowadays, you know. Well, chickens even before they are hatched need pure air as much as they do after they are hatched. If you love the chickens, and even a contrary sitting hen, and keep due watch, you can wash off the eggs in hot water; and if it has not been on too long the chicks will hatch out all right. This breaking of the egg not only soils the other eggs and the mother hen, but it gets a whole lot of fowls into the habit of eating their eggs; and if they once get into that habit you may finally be obliged, in desperation, to get a sharp hatchet for a remedy. Somebody says that broken eggs and filthy nests harbor vermin. I have good reason to believe that many a severe attack of hen fever has resulted in a disgust and dislike for the whole chicken business just because of a little carelessness in the start in letting a hen break her eggs. Well, what is the remedy? It has been suggested to me by a good friend whose letter I append at the end of this talk. She says "plenty of litter." But that is not all.

I have been watching sitting hens quite a little lately, and have finally succeeded in getting some pretty fair hatches. I confess I do not *know* how to make the very best kind of nest; but when I explain to our readers my conclusions they will, perhaps, tell me of something better than mine. First you want the right kind of box to hold the material. In the summer time I suppose a box without a bottom would be better; but as we often want to carry these nests around, hen and all, to some other place, I suggest that a bottom made of inch poultry-netting would be the right thing. This would let the fine litter sift through. Now, I would have the box about 15 inches wide and 30 long. Many of you will say this is too large, beyond all reason. Just wait a bit. If you have this poultry-netting for a bottom, chaff will not do. You want some soft straw—at least

---

\* When I heard of this friend's sudden death I could not help thinking of Luke 12:20, where God says, "This night shall thy soul be required of thee. Then whose shall these things be which thou hast provided?"

I do not know of any thing better than that. The loose straw that has been trampled up so it is soft and loose will do very well. Perhaps clean oat straw that has been used for bedding would be about the thing. The hen will fix it herself better than you can do it for her. The nest ought to be shaped about like a wooden bowl—not so deep in the center that the eggs will pile up on top of each other, and not so flat that they will roll off into the corners of the box. The corners of the box should be well filled with straw packed in hard. I do not know but the right kind of wooden block nailed in the corners would be a good thing so as to make the interior of the box to a great extent bowl-shaped, say about like a common wash-basin.

Give the hen enough straw so she can toss it over her back and tuck it up nicely around her. Now, if your straw is soft enough, and if there is enough of it between the eggs and the sides and bottom, she can not very well break an egg. The eggs will sink down into the soft straw out of her way before they break; and in order to have plenty of room for material I would have the box about 8 inches deep inside.

We all know that hens like seclusion; and I have studied somewhat as to how to cover this nest so as to give about the kind of seclusion a hen wishes. Another box just like the one I have described, but only half as long, placed upside down over the nest, seems to be about the right thing. The nest should then be in the back end of the lower box; then the hen, to get in, steps down in the open end and walks over to the end that is covered. If she is a large hen perhaps you had better cut out the end of the upper box, say in the form of a half-circle, in order to let her get over the eggs with less trouble. And, by the way, this upper box must be fastened in some way to keep it in place. If it is hinged with leather or metal hinges on the back end of the lower box this will make a very nice arrangement. Any style of nest with a cover over it should permit of the easy removal of said cover. If an egg is broken you want full access to all the eggs, litter, and every thing else in order to clean them off. With the nest I have described you can set your basin of hot water in the end of the box opposite the nest; then your eggs can be quickly cleansed and put back on clean straw. If the water is up to 100 or 103 it will not chill the eggs at all, and the heat will dry them off when placed on clean dry straw by the time you are through. Now, if Biddy has got her feathers soiled, *she* ought to be washed off too.

May be you will say if we have got to have all this fuss with sitting hens we had better get an incubator; and I confess an incubator is much nicer to work with than a sitting hen—especially one of the pugnacious kind; but if your nest is made right, as I have tried to direct, I do not think you will very often have to wash off the eggs.

Just a few days ago I found a sitting hen in a box without a particle of straw. She had broken all of her eggs but six at different times, and not one of the six hatched a chicken. All this worry and bother, with nothing to pay for it, just for the want of a handful of the right kind of straw!

I would not have this nest in the yard with other hens if I could help it. No other hen should

be allowed by any possibility to get on when she is off. Place the box and all in a little yard by herself where she has feed, water, and gravel. This is much better than letting her be annoyed by other hens. But I do not like that as well as letting her have her liberty to go where she pleases and to stay off the nest as long as she chooses. I have several times had hens hatch and bring out eighteen chickens; and they always had a convenient nest, and had things largely their own way.

Do not let any one persuade you that there is a patent on making a little yard for each sitting hen, or on having an arrangement so the door shuts while the hen is on. All such devices are pictured and described in poultry-books printed years and years ago. Trap nests are a good thing on some accounts with sitting hens; but I do not like any of them as well as the simple box I have described. The little house like the one pictured on page 638 of last GLEANINGS is a very nice place indeed for a sitting hen. You can put the sitting hen upstairs, where it is an easy matter to handle and look after her. Where you have a lot of chickens in a fireless brooder downstairs, the doors and poultry-netting make it a very easy matter to give the sitting hens all the conditions that may be required when we have all kinds of weather unexpectedly. Now read the following letter from a good woman who not only succeeds with *poultry* but in managing a whole farm after the death of her husband:

*Mr. A. I. Root.*—My sister, who is interested in bees, subscribes for GLEANINGS and she has read to me your articles about the chickens, which have given us many a good laugh, and I believe there is nothing better for people who are hard at work than laughter; so, please give us more, for you are doing missionary work. You asked for the names of women who make a specialty of selling day-old chicks. Now, I do not make a specialty of that branch, but this season have advertised chicks hatched with hens, the mother to go along if necessary to care for them. My sister and I are city women who came to this farm four years ago, when my husband died, and engaged in the difficult but always interesting task of building up a run-down farm—a beautiful old place of 42 acres situated ten miles from Buffalo. My expenses are heavy, as I hire two men by the year, and a girl for the housework. We all work all the time, and my brains are "worn thin" with hard thinking over the best way to manage affairs, and the various problems which are continually arising. Many of the difficulties of the first years have been overcome; and a growing income, together with an increasing number of satisfied customers for our produce, gives us confidence to keep on, although expenses will not be materially lessened until the farm is made to produce better crops. The soil is good, but has been robbed for many years. I have an acre of fine alfalfa, and mean to have more. If I keep on with a dairy it is a necessity.

The chickens have proved a profitable branch, even with buying nearly all the feed. I winter about 300 hens, get my chickens out in March and April, usually hatching about 1000, and thus have broilers when prices are high, and pullets for winter laying. I also sell eggs for hatching, and have been successful in the show-room. I have one incubator, a 300-egg model, and I am frank to confess that the hatches are far from satisfactory, as 60 per cent is the best one. The very early hatches bring out only about 25 or 30 per cent. This year, with 243 February eggs I got 55 chickens, while hens from the same stock hatched nearly 75 per cent out of 60 eggs; and I know that incubators are a necessity, but I regret the necessity. I acknowledge all the shortcomings of the hens, and it is exasperating to have them break eggs and step on the baby chicks; but after all, one is working more in harmony with natural laws, wherein there is strength.

This year I have 30 hens sitting in the house cellar where there was a furnace fire early in the season. This took the chill from the air. The nests are roomy, and filled with oat chaff and a little straw. One can not be too careful to give plenty of litter, as the hens scratch it away in the center and leave the eggs on the bare boards, which makes her break them. Every morning the hens are lifted from the nests, fed, exercised, and replaced. They are each marked with strings on their legs. It takes more time than an incubator, out it pays. Of course if one were hatching chicks by the ten thousand I suppose this method would be impossible. I never give hens over 13 eggs.

I could talk chicken all day, for I dearly love to work among them. The only part of the business that I do not like is having them killed. It does not seem right to kill the pretty gentle creatures, and it always makes me uncomfortable. I should like to know the actual percentage of eggs hatched in incubators at the Bloom establishment very early in the season, and whether their incubators are heated with hot water or air. Unfortunately, in most of the advertisements for incubators, exceptional hatches are made the basis for their claims, and naturally the numerous failures are unmentioned; and it is a satisfaction to have, if possible, authentic reports direct from such a business as you describe. I think there should always be a cover over their heads, which gives them the sense of seclusion they love. In all classes of live stock, over-stimulation in any direction brings a corresponding reaction, and often results in disaster. My cows are out every day in winter. I have healthy lively calves to sell for breeding, at good prices; and if, instead of the interminable discussions in regard to tuberculosis, the farm journals would all preach "fresh air, fresh air, fresh air," and exercise for all domestic animals, there would certainly be less disease, and city people could drink a glass of milk without a shudder. Probably after a while they will be afraid to eat fresh eggs, but so far there is no trouble on that score. This free open-air life has been the salvation of my physical health, and my sister Louise wishes you could have some of the beautiful spring water near here, which has been a powerful factor in my recovery.

MRS. STEPHEN WALKER.

Williamsville, N. Y., May 7.

#### SPROUTED OATS; MORE ABOUT IT.

We clip the following from *Commercial Poultry* for May:

Hens will lay as well, and perhaps better, when kept in confinement than when on free range, if all their requirements are met; but if they are restricted to one or two kinds of grain, with no meat, grit, dust bath, shells, or exercise, and poor water, their production will be small. Green food must be supplied them, and this can be grown, as mentioned above, or it can be served in the form of sprouted grains, which are highly esteemed as an egg-producing food.

More than twenty years ago the value of sprouted grain was recognized by a few, and the process of preparing it published in the agricultural and poultry papers; but owing to the work involved it never became popular. Some years ago the *Reliable Poultry Journal* published an account of the method employed in Ireland—how they sprouted oats in boxes for the growing stock. This method was hooted at by some of our leading poultry-keepers who are now feeding sprouted grain to hens in confinement, and some even assert that it can be made the principal feed. That it does solve the question of green food, and makes it possible to keep poultry in more limited quarters than ever before, there can be no doubt.

Some place great stress on the cheapness of this feed, as a bushel of grain, especially oats, when sprouted, will increase in bulk and make four bushels; thus a bushel of oats costing sixty cents will make four bushels of feed, the cost being but fifteen cents per bushel. It is not, however, a cheap feed: it requires considerable labor to prepare. The increase is not as great as where the grain is sown in the ground, neither is there as much space required; but the labor to sprout a single bushel of oats is as great as to sow and harvest the same.

Grain can be sprouted in almost any place where it will not freeze. The warmer the place the better. In winter a warm cellar or workroom can be used; and in summer, if no better place affords, it can be done out of doors. It is best to have racks for this purpose. A frame of 1x3-inch stuff, set edgewise, 4x4 feet, with a partition in the center, is first made. To this frame securely nail lath, placing them from  $\frac{1}{8}$  to  $\frac{1}{4}$  inch apart. This makes a box 4x4 feet, three inches deep, with a slatted bottom and a partition in the middle. The center partition is only for the purpose of strengthening the lath. The lath should be soaked in water over night so they will not split when nailing. The number of these racks required will, of course, depend on the number of fowls to be fed.

Place the grain to be sprouted in a tub and cover with water (warm water is best) and allow it to soak for twenty-four hours. Pour off the water and let them drain for half a day, then cover the racks with old bran-sacking, single thickness, and spread the grain upon them to the depth of about two inches. If space is limited, the racks can be piled one upon another; and if out of doors a cover should be made for them that will turn rain. Night and morning the racks are taken down and the grain sprinkled with hot water, the hotter the better, using a hand watering-pot or spray-pump. The racks can then be replaced. It does not matter if the water in the upper racks drains down into those beneath, as it will all run off in time. In from ten days to two weeks, depending on the temperature, they will be ready to feed. When in proper condition for feeding, the sod will be three or four inches thick, and the growth of green food on top of this, four to six inches high. When feeding, give a block about a foot square to fifty hens. Each rack holds about a bushel and a half of grain before sprouting, and will make sixteen feeds for

fifty hens. It will answer the purpose of one grain feed and green food. With a block of this fed in the morning, corn and wheat at night, and a mash meal, grit, shells, and beef scrap in hoppers where the hens can supply any deficiency, a good, simple, and inexpensive ration is served.

I do not quite agree in regard to the expense of these sprouted oats. Where facilities are at hand, say on a farm, and land is cheap, it is, no doubt, a better way to sow oats every few days in the open ground, and let the chickens dig them out; but sprouting them in crates can be done evenings or during bad weather; and it can all be done in the cellar or in any out-building during warm weather. Where hens must be kept in confinement, sprouted grains are, without question, *the thing* to keep up a properly "balanced ration."

After the above was dictated I found the following in the *Rural New-Yorker* for May 23:

#### SPROUTED OATS FOR CHICKS.

A recent issue of the *Rural New-Yorker* gave Mr. Cosgrove's method of supplying hens with green food in winter. We get an ample supply at a minimum cost from sprouted oats. A furnace in the cellar or other warm place is necessary for the operation in winter; we expect to continue it this summer out of doors. The oats are placed in a water-tight vessel and covered with warm water, and allowed to stand 24 hours, when they are emptied in a box that will allow the water to drain off freely. Oats are left in this box, and wetted twice a day with warm water until the oats have sprouts a quarter of an inch long, when they are spread in boxes about one inch deep. The sprinkling is continued until the oats are as large as you desire. We usually use them when four or five inches high. The hen will eat the roots as well as the tops. With a temperature of 60 degrees, ten days will bring this result; so after the first start this green feed can be provided for each day. Chicks will eat the oats when a week old, and leave all other feeds for them. As the fowls all prefer the oats to green clippings of fresh-cut lawn grass, I shall continue the feeding of sprouted oats all summer. Since using this method of getting green food I learn that this information is being sold as a secret for \$5. As we were using this method before we heard of our friend with the \$5 secret, we feel free to offer it to your readers, having obtained the idea from the Chinese in San Francisco in 1870. The green color can be given to the oats by one day's exposure to the light. They grow as freely in the dark, and the boxes can be stacked over each other if short of room. I believe this to be the cheapest green food that can be given in the winter.

JESSE B. UPSON.

Illinois.

Some of the friends may think I am giving a large amount of space in a bee journal to this matter of sprouted grains; but after you have once made a test of it you will find it is well worth attention. It just occurs to me that the man alluded to, with his \$5.00 secret, has done the world a considerable service after all, even if the thing was not entirely new when he brought it out, for he with his persistent advertising gave it a wide publicity that it might not have had otherwise.

#### THE FIRELESS BROODER A SUCCESS IN UTAH.

I am using the fireless brooder, and like it far better than the ones used with artificial heat.

H. A. PINEGAR.

Wellington, Utah, May 12.

#### TWO INTERESTING BULLETINS.

THE United States Department of Agriculture has just issued two bulletins which are of interest to many bee-keepers. One (323) is entitled "Clover Farming on the Sandy Jack-pine Lands of the North." The other (No. 325) is "Small Farms in the Corn Belt." We think both bulletins are free. Apply to the Superintendent of Documents, Washington, D. C. W. K. M.

## THE DANZENBAKER SMOKER

PAT. OCT. 3, '05, JUNE 4, '07

### GOLD MEDALS

St. Louis Exposition, 1904  
Jamestown Exposition, 1907

IS THE BEST,  
STRONGEST,  
COOLEST,  
CLEANEST,  
CHEAPEST,  
AND LARGEST  
SMOKER SOLD  
FOR A DOLLAR

The perforated side grate seen above holds a removable, metal, asbestos-backed fire shell, preventing burning the tin off the outer case, and deflects the air at right angles, preventing back draft to the valveless bellows. The air, passing to the back and over the top, cools and expels the smoke, fanning the burning fuel at top or side till all consumed, giving cool smoke for hours from one filling. It can't clog. No top-heavy cap to choke with soot; no valve to fail; no holes shedding sparks or hot ashes.

Four years' sales prove its success beyond a doubt, expensive dies making it uniformly perfect as possible to devise. We confidently guarantee full satisfaction or refund the price.

Price, \$1.00; 3 for \$2.50; by mail, add 25c. each

Send address of yourself and Bee friends for 8-page leaflet on "Smoker," and facts about Bees and Queens, 80 pages, free.

F. DANZENBAKER, Norfolk, Va.

# TO LAND SELLERS

There is a continual demand for farms or ranches suitable for bee-keeping. If you have the right kind of place, and can satisfy us on that point, we are certain you can dispose of it to one of the 35,000 readers of GLEANINGS IN BEE CULTURE, by inserting a small advertisement in its pages.

There is no other medium by which you may reach the great constituency of bee-keepers. The cost of such an advertisement is small when compared with the results.

## Big Stock of Root Co. and Marshfield Co. BEE-SUPPLIES AT FACTORY PRICES

to close out on account of poor health. Parties sending me cash order for \$15.00 or over before June 30, I will give 10% off. If not enough in stock to fill order, will order balance from factory and give 5% off on same.

S. D. BUELL, . . UNION CITY, MICH.

## Convention Notices.

The third field day of the Massachusetts Bee-keepers' Society will be held at Littleton, Mass., by invitation of the former President, Mr. F. H. Farmer, on Saturday, July 18. Come with your friends and have a pleasant day. Try to come on forenoon trains, which leave North Union Station at 8 and 11 o'clock. This is a basket-lunch picnic. Fare from Boston, 60 cents each way; ten-ride tickets, \$6.30. It is impossible to give exact time of trains, as the new time-table does not go into effect until June 22. There are several forenoon trains, also an afternoon train at 2:10. We expect to meet members from the Worcester County Society there. Practical demonstrations will take place. Belmont, Mass. X. A. REED, Pres.

The ninth annual meeting of the Texas Bee-keepers' Association will take place at the Farmers' Congress at College Station, Texas, on the grounds of the A. and M. College, July 8, 9, 10. There will be many topics of special interest to bee-keepers this year—serious questions in which all who can should take part. Several new features will be introduced in the program also, the chief of which is that of practical demonstrations instead of the heretofore many long papers that were read before the conventions. The question-box is always to be open, and all are asked to help make this the liveliest meeting of bee-keepers that Texas has ever had. Low rates of transportation, attractive grounds, good entertainment, and reasonable meal rates, help to make the attendance both pleasant and profitable. There will be exhibits of bee-keepers' products, for which special premiums will be awarded, so that all are requested to send what they can. All information may be obtained from Louis H. Scholl, New Braunfels, Texas. The following is a copy of the

### PROGRAM.

Call to order; prayer; President's address; reception of new members; general business.

Location of apiary.—W. C. Conrads, New Braunfels; W. E. Crandal, Floresville.

Where to commence preparation of apiary for a honey-flow.—D. C. Milam, Uvalde; Willie Atchley, Beeville.

Foul brood in Texas, and what to do with it.—Prof. Louis H. Scholl, New Braunfels.

Prevention of swarming, and increase.—F. L. Aten, Round Rock.

Best methods of queen-rearing, and success with baby nuclei.—W. H. Laws, Beeville; John W. Pharr, Berclair.

Production of extracted honey.—T. P. Robertson, Bartlett; O. Sueltenfuss, San Antonio.

Marketing honey.—Udo Toepperwein, San Antonio.

Is it profitable to have apiaries in another State?—W. O. Victor, Hondo.

Comparative profit in the production and sale of extracted chunk comb and section honey.—A. H. Knolle, Hondo; Hugo Sattler, New Braunfels.

Bee-keepers' exhibits at fairs.—Dr. C. S. Phillips, Waco; J. M. Hagood, Enloe.

The value of hives made from Texas pine.—W. H. White, Blossom.

Report of the College apiary.—Prof. Ernest Scholl, College Station.

Report of committee on awarding premiums, etc.

Election of officers, and completion of all business that should come before the association.

The question-box will be taken up at each session.

F. L. ATEN, Committee on Program.

LOUIS H. SCHOLL, Sec'y and Treas.

### CHEAP LUMBER

The Gordon Van Tine Company are now prepared to supply buyers with all kinds of ordinary lumber for building purposes at sawmill prices. Car lots may be purchased and delivered anywhere in the United States at one-third under dealers' prices for similar quality.

If you intend to build a house or barn, factory, church, store building, or any other structure, send the list of material to the Gordon Van Tine Co. for an estimate of cost.

You may also obtain an immense free catalog of 2000 items, simply by sending a written request for it. Address all correspondence to Gordon Van Tine Co., 763 Case St., Davenport, Ia.

## CLASSIFIED ADVERTISEMENTS

Notices will be inserted in these classified columns at 25 cents per line. Advertisements intended for this department can not be less than two lines, and should not exceed five lines, and you must say you want your advertisement in the classified columns or we will not be responsible for errors.

Breeding queens of pure Caucasian and Carniolan races—price \$3.00. Order from A. E. Titoff, Expert in Apiculture, with Russian Department of Agriculture, Kieff, Russia. Remit with orders. Correspondence in English.

# SPECIAL NOTICES

By Our Business Manager

We have had a number of shipments of queens direct from Italy, and in every case they have arrived in first-class shape. In fact, their condition is very remarkable, and we do not recollect ever receiving them so uniformly good. If you are on the outlook for young vigorous imported queens we have them.

## ONE-FRAME OBSERVATION HIVES.

We still have a few slightly shop-worn observation hives, one-frame, with super, which sell for \$3.00, which we offer to close out at \$2.40 each.

## FOUNDATION SPLINTS.

Some have been writing Dr. Miller for foundation-splints. He does not have them for sale. We are prepared to furnish them for 10 cts. per 100, 50 cts. per 1000 postpaid, or 40 cts. per 1000 with other goods.

## FIRE AT ST. PAUL BRANCH.

Just as we go to press we have a despatch advising of a fire damage to St. Paul stock. Particulars are not at hand. We are shipping them a car of stock, and they will doubtless soon be in shape to take care of orders as usual.

## HIVE NUMBERS.

We can supply hive numbers with figures  $1\frac{1}{8}$  inches high, printed on tough cardboard, then boiled in paraffine so as not to be injured by the weather. They may be fastened to the hive with tinned tacks. We have them in sets up to 400 numbers. Price \$4.00 per set postpaid, or \$3.50 with other goods; 100 postpaid, \$1.15, or \$1.00 not prepaid; 50 postpaid for 65 cts.; not prepaid, 60 cts.

## BEESWAX.

For good average beeswax shipped before the end of June we will pay 29 cts. per lb. cash, or 31 in trade delivered here. The season is so far advanced that we make this raise of 1 ct. per lb. for two weeks only, because we do not want to stock up at the close of the season at high prices. If you have any to furnish send it on at once and secure this temporary rise in price.

## ROOT'S WEED FOUNDATION.

During the month of May we shipped over 33,000 lbs. of comb foundation, which is about 9000 lbs. ahead of our best previous month in this or any former year. The aggregate of our shipments for April and May is also in excess of the same months in former years. This goes to show that we are pushing out goods at a rapid rate in our efforts to supply the excessive demand this season.

## PROMPT SHIPMENTS.

In spite of our best efforts a goodly number of our customers, for orders sent here as well as to some of our branch houses and agencies, have had to wait longer than seemed to them reasonable. Conditions are about normal again; and as we go to press we are much closer up on orders, and prepared to give prompt service. Hives are still in demand. At no time have we been short on sections. We have a good stock ready for immediate shipment, and are turning out new stock at the rate of over 2,000,000 per month. We are well supplied with most sizes of shipping-cases. If in need of goods promptly, send on your orders.

## SIMPLEX HONEY-JARS.

center being cut out.

The factory people have advised us of a carload of these jars as already on the way to us, with more to follow in due course. By the time your order reaches us we shall have a supply in the warehouse, ready for instant shipment. They will be packed in reshipping-cases of two dozen each, and the price will be \$1.10 per case; six cases, \$6.30.

## NO. 25 HONEY-JARS.

During the past year we have had an unusual amount of trouble with breakage of this jar, even in the reshipping-cases packed with corrugated paper. The breakage occurred either in the porcelain cap or the top rim of the jar where the cap rests. We find we can get this same jar with lacquered tin cap without the breakage. This cap is lined with a waxed paper

wad which seals tight on the top edge of the jar. This style of cap not only does away with nearly all breakage, but enables us to furnish the jar at a lower price. We are now ready to fill orders. They will be packed as usual, two dozen in reshipping partitioned cases. No. 25 jars, tin cap lined, 90 cts. per case; 6 cases, \$5.10. We can still furnish from stock the usual style of No. 25 with porcelain caps at \$1.10 per case; 6 cases, \$6.30.

## SPECIAL DANZ. SUPERS.

Of the special Danz. supers offered from Floresville, Texas, we still have to dispose of 80 to 90 in which little can be counted on for sections and foundation starters; otherwise they are complete regular Danz. supers,  $16\frac{1}{2} \times 20$  outside measure, fitted with Danz. section-holders, H. S. M. fences and springs, nailed and painted; worth from regular stock \$1.00 each; will sell them at \$5.00 for 10, or the lot at 40 cts. each.

There are also 400 shipping-cases for 20 Danz. sections, put up 50 in a crate, which we offer at \$6.00 per crate or \$10.00 per 100 for the lot. These goods, of course, are offered subject to previous sale, and should be taken quickly at these prices.

JAPANESE BUCKWHEAT.

The season for sowing buckwheat is at hand. We have a choice lot of seed grown for us last season, which we offer, bags included, at 15 cts. per pound, postpaid; not prepaid, 5 cts. per lb.; 45 cts. per peck; 85 cts. per half-bushel; \$1.50 per bushel; 2 bushels, \$2.50; 10 bushels, \$11.50.

## SECOND-HAND FOUNDATION-MILLS.

We have to offer the following second-hand foundation-mills in good condition. We shall be pleased to hear from any one interested. To such we can send a small sample of comb foundation representing the kind of work produced by the particular machine you inquire about.

No. 079.— $6 \times 2\frac{1}{2}$ -inch hex. cell thin-super mill, in very good condition. Price \$12.00.

No. 078.— $6 \times 2\frac{1}{2}$ -inch hex. cell thin-super mill, in good condition. Price \$12.00.

No. 086.— $6 \times 2\frac{1}{2}$ -inch hex. cell extra-thin-super mill, in good condition. Price \$12.00.

No. 075.— $2 \times 9$  hex., very old style, on frame with wood base; in fair condition. Price \$10.00.

No. 085.— $2\frac{1}{2} \times 6$  hex. thin-super mill, in good condition. Price \$12.00.

No. 086.— $2\frac{1}{2} \times 6$  hex. extra-thin-super mill in extra-good condition. Price \$15.00.

No. 096.— $2\frac{1}{2} \times 10$  hex. light-brood mill; almost new; in fine condition. Price \$20.00.

No. 097.— $2\frac{1}{2} \times 10$  hex. light-brood mill; in fine condition. Price \$18.00.

No. 077.—10x2-inch medium-brood round cell, old-style frame, in good condition. Price \$14.00.

No. 092.—6x2½-inch hex. cell extra-thin-super mill, in fine condition. Price \$15.00.

No. 2275.—6x2½-inch hex. cell extra-thin-super mill, in good condition. Price \$13.00.

#### BEES AND QUEENS.

Everybody nowadays, with any pretensions to success, tries to keep pure-bred stock, whether it is horses, cattle, swine, poultry, or bees. With mongrels you are working in the dark. Pure-bred stock of any kind is a credit to all concerned—breeder, dealer, and purchaser. We have tried to keep the best stock possible; and that we have succeeded is best borne out by the testimonials we have received and are continually receiving from customers. Here is a sample testimonial (we have others).

Streator, Ill., June 5, 1908.

A. J. Root Co.—My hive and bees I have received. I received the hive Wednesday and bees Thursday. I have them in their new chaff hive. They cost me \$22.25, but I would not take \$50.00 for them; well pleased; without doubt the nicest bees I ever saw in my life.

Yours truly,

HERSCHEL E. MOFFITT.

If you wish to breed bees for sale or show purposes you must have fine stock to begin with. A discriminating public will have no other. We are always ready to quote reasonable prices for fine stock in large lots. We do not breed the other kind. Now is the time to purchase bees.

| 1-fr. nucleus without queen         | \$3 00        | \$2 00       |
| 2-fr. nucleus without queen         | 4 50          | 3 00         |
| 3-fr. nucleus without queen         | 5 50          | 3 50         |
| 5-fr. nucleus without queen         | 6 50          | 4 50         |
|                                     | Oct. to July. | July to Oct. |
| Col. in 8-fr. Dov'd hive, no queen  | \$10 00       | \$7 50       |
| Col. in 10-fr. Danz. hive, no queen | 11 00         | 8 00         |
| Col. in 10-fr. Dov'd hive, no queen | 12 00         | 9 00         |

We can supply with the nuclei any of the queens mentioned in list. When one buys an extra-select queen, or any high-priced queen, he would do well to have her come in a nucleus. This will assure safe arrival.

## Special Notices by A. I. Root

#### "LYDIA E. PINKHAM" AND FAKE TESTIMONIALS.

We are rejoiced to learn by the *Mail Order Journal* for June that the Lydia E. Pinkham Co. has been fined \$6000 for using the photograph of a young lady, together with a *forged* testimonial in favor of their medicine, without the permission or knowledge of the young lady whose photo was used. Now, if this will establish a precedent so the Duffy whisky people and all medicine companies can be prosecuted likewise, we can all "rejoice and be glad." Heretofore it has seemed that this sort of forgery could not be reached by any existing laws; but I think it is high time that these medicine-swindlers be taught better.

#### THE WRIGHT BROTHERS AND THEIR FLYING-MACHINE.

Since the report in our last issue, the elder of the Wright Brothers has gone to France. The following, clipped from the *Woman's National Daily*, gives a glimpse of what is going to be done:

PARIS, June 2.—One of the men associated with Mr. Wilbur Wright in the aeroplane trials that are to take place in the north of France said to-day that Wright was confident of meeting conditions laid down by Lazarre Weiler, who has offered \$100,000 for the Wright aeroplane if it will make two flights of 50 kilometers within a week, carrying two passengers and enough gasoline for a 200-kilometer flight, or ballast equivalent to this. "I have already equalled this distance," said Mr. Wright, "in the flights at Manteo, N. C. Fifty kilometers is 31 miles, and I shall be disappointed if I do not sail further than this in a single flight. Our machine has sailed with two passengers, though we have never carried a weight equal to that imposed by Weiler."

With what is now going on in other parts of the world with successful flying-machines, I think it is quite likely that some of us, at least, will see them going over our heads before another winter.

#### THE "STAINLESS-FLAG" PAMPHLET.

I find we have at present something like 200 copies left, and therefore we can not undertake to furnish in the future more than one copy to each applicant. If you did not get one last year, and would be glad to see a copy of this great temperance tract, let us

know and we will mail you one as long as they last. If you should be in need of more than a single copy, apply to your own State Superintendent of the Anti-saloon League. I think the 100,000 copies or more, distributed, of this temperance pamphlet have had much to do with the great prohibition wave that is now circling not only all over our land but all over the world.

#### THE ACME HAND POTATO-PLANTER.

As we are now out of the seed-potato business we offer about four dozen Acme potato-planters at a big bargain to close out.

To those who are not familiar with them we will say that this machine makes the holes, and drops and covers all at one operation. Once over the field does the work when the ground is fitted. In the soft soil of Northern Michigan, the great potato region, one expert man or boy will plant two acres in a day. Up there the potatoes are nearly all planted with this little implement. A year ago we offered them at 55 cents each, or three or more at 50 cents each, or one dozen for \$5.25. While they last we will make you a price of 45 cents each, or three planters for \$1.20, or a crate of 12 for \$4.00. If you want them at the above price you had better get your order in before they are gone.

#### "A LITTLE LAND AND A LIVING."

The above is the title of a new book, just out, by the author of "Three Acres and Liberty." It is along the same line with what I have to say in our book on tomato culture, about supporting a family on a quarter of an acre. The book is specially valuable because it gathers up a great number of illustrations taken from the various agricultural periodicals in regard to what can be accomplished on a little piece of land—or perhaps I should say in regard to what has been accomplished. As the dates and references are all given, it is an easy matter to verify these statements, telling us what is possible to be done on a little piece of ground by one who is *really in love* with old Mother Earth. The only thing that troubles me about recommending books of this kind is the fact that many people forget that these good results are accomplished only by indefatigable labor, early and late. The price of the book is \$1.00, and can be had by addressing the Arcadia Press, 150 Nassau St., New York, or from this office.

#### THE ROMANCE OF THE REAPER.

On page 585 I said it was impossible for me to read or even look through very many of the books and papers which the kind friends are sending me day by day; and I have been thinking for some time that I should probably not read many more *books* clear through. But I had one of my happy surprises when I got hold of a little book of 184 pages, entitled "The Romance of the Reaper." The book was first issued serially in *Everybody's Magazine*, with which many of you are familiar. Its beautiful print, making it easy to read, and its magnificent illustrations, caused me to read it almost from beginning to end without any tired or "sluggish feeling" in the least. One reason why it took such a mighty hold on me was that, for the first time in my life, I fully comprehended how the evolution of the reaper has helped to feed the starving multitudes all over the face of the globe. It also appealed to me particularly because I can well remember seeing in my boyhood days the mower introduced, later the reaper, then the binder that used wire, and finally the *twine* binder. The history of these great inventors, who worked day and night unflinchingly for a term of years, reminded me most vividly of the evolution (in our own industry) of the honey-extractor and the present hives and appliances that we have for producing comb honey. The book does not give *any one man* the credit by any means; but we have most interesting sketches of a score of great inventors who helped to make the reaper what it is now, and also who helped to make the *farmers* of our land what they are now. The book is beautifully written by Herbert N. Casson, whom I should pronounce one of the most talented writers of the present day. There are passages in certain parts of the book that would do credit to a Fourth-of-July orator. The price is \$1.00, and I do not know how you can invest that amount to better advantage. Read it yourself, and then lend it all over the neighborhood. In some places it seems to defend the trust business; but if great trusts have been the means of feeding the hungry in the uttermost parts of the earth we can thank God for this one thing at least. If some of the millionaires who have more money than they know what to do with should all at once take a notion to use some of their means to feed the starving *women and children* in the different corners of the earth, I should certainly feel that the millennium is coming. So far as I can learn from the book, I believe our great inventors of reapers and mowers, most of them if not all, reaped a rich pecuniary reward.

The book is published by Doubleday, Page & Co., of New York, to whom letters of inquiry should be sent.

JAMESTOWN, N. Y.

# TO OUR PATRONS

For the convenience of our patrons we some time ago established a series of agencies in the principal business centers of this country, chiefly with a view to the much more expeditious shipment of goods. Every one knows, who has much to do with railroads, that they are provokingly slow just at the very time the buyer is waiting for the goods. This is particularly true of bee-keepers who do not know what their requirements will be until the season has almost arrived. Then they order the goods in a great hurry, expecting to get them in a few days, whereas the railroad people consume weeks in getting the goods to the destination. To overcome this we have covered the country with agencies. Some of these are our own, and some are not. It is immaterial to the consumer which is which, for they all sell (or nearly all) at our Medina prices. They can do this because the charges on a carload of bee-supplies are small compared with the individual charges on small lots. There are other advantages. Many can go to some nearby city and purchase the goods *after* having inspected them. Others drop in to have the uses of the various apian articles explained.

## OUR NEW YORK BRANCH.

This branch was established chiefly to take care of our foreign trade, which had grown to large dimensions, and which we found impossible to cope with from Medina alone. We have made no effort to draw local trade to this office because we have branches at Syracuse and Philadelphia, but in spite of ourselves a trade has grown up tributary to the city of New York. Persons doing business in the metropolis, but living in the suburbs, found it very convenient to call at our office and order their supplies as needed. Others living at a considerable distance from the city, but who occasionally visit it on business, took the opportunity to call and see us, and in consequence gave us their business. The office is located in the *Evening Post* building, opposite St. Paul's Church, and just around the corner from the old Astor House. It is near the postoffice.

We have no stock of goods there, the warehouse being located in Hoboken for convenience to the shipping. The address is Evening Post Bldg., Vesey St., Telephone 543 Cortlandt.

## OUR PHILADELPHIA BRANCH.

This is in charge of William A. Selser, a veteran in the bee business, and a prominent authority on the subject of honey. Having been so long in the business, all the time in the vicinity of the Quaker City, Mr. Selser is peculiarly able to give assistance and advice to beginners and others not so well informed perhaps. Usually we carry quite a stock of goods there, wherewith we supply Eastern Pennsylvania, New Jersey, Maryland, and Delaware, and even points much further away. Twice a week during the season the manager gives lessons to persons who wish to see how various appliances are used. For this purpose the spectators need not leave the building as we have an apiary on the roof. We also have other large apiaries near the city where are bred bees and queens. Here we have had "field days" when as many as 1000 bee-keepers assembled to see some of the leading experts do stunts with bees. This shows the strength of the bee-keep-

ing interests in and round Philadelphia. If you can make use of this branch we shall be glad to have you do so, as our facilities are full and complete in all departments. Mr. Selser has a big fund of information to draw on, and is at your service. The address is The A. I. Root Co., 10 Vine St., Philadelphia.

## THE WASHINGTON BRANCH.

This branch was established to cope with the trade of Virginia, Western Maryland, and adjacent territory. Contrary to general opinion, the capital city of our nation is very favorably situated for business purposes. This is more particularly true of Virginia and Western Maryland, which can be served with great promptitude and despatch by the railways from Washington, also by way of the Potomac River steamers. Lately this branch has been greatly favored with orders, and we judge from this our friends have found out its value as a shipping-point. Our manager there is Mr. W. T. Kerrick, an experienced bee-keeper. This office is situated at 1100 Maryland Ave., S. W., and may be easily found by strangers on a visit.

## OUR CHICAGO OFFICE.

As the greatest railroad center of the world, it was long manifest to us before we actually decided on it that we ought to have a branch establishment in Chicago from which we could ship orders that are needed in a great hurry. In a number of other ways there are great advantages in having a Chicago warehouse, chief of which is the opportunity of being able to ship on the very railroad near which the bee-keeper lives. This insures better service, quicker transport, and lower rates. Then, again, many of our customers who perchance may visit the city find it convenient to call on us, and in this way we become more conversant with their wants and desires. We need not enlarge on the advantages of this office, as they will be obvious to most of our readers who live in the region tributary to Chicago. Our manager there is R. W. Boyden, who is always on hand to attend to the wants of our friends, and who is very glad to see callers who are interested in bee-keeping. The office address is, The A. I. Root Co., 144 E. Erie St., Chicago, Ill.

## THE A. I. ROOT CO. IN SYRACUSE.

Here we have in complete charge Mr. F. A. Salisbury, whose name was familiar to American bee-keepers 25 years ago, and has been ever since. He has many friends who enjoy sending him an order every year with clocklike regularity. Syracuse is right in the heart of a bee country, and last year when every one else was complaining of "hard times" Mr. Salisbury did quite his usual amount of business, possibly a little more. Much of this is due to his personal qualities as a business man with years of good reputation behind him. He is, in addition, situated in a fine business center so as to reach New England and New York. He also knows the importance of getting out orders in a hurry when the honey-flow is in sight. He has been there himself, and has a fellow-feeling for the belated customer who leaves off ordering to the last moment. The A. I. Root Co., Syracuse, N. Y., is sufficient.

The A. I. Root Co., Medina, O.

### READ WHAT EXPERTS SAY OF IT

The Christmas mail brought me what is probably as useful and beautiful a Christmas present as I ever received—a morocco-bound copy of the new edition of the A B C and X Y Z of Bee Culture. Bee books and journals have come to my desk of which it seemed as though the least said the better. Not so with this book. On the contrary, it seems as though words were lacking to do it justice. There are many other bee-books, each filling its niche, but, in all the world, there is nothing so comprehensive as the A B C and X Y Z of Bee Culture. There is no point in the wide domain of apiculture that is not touched upon in this volume, and the information is the very latest and most authentic, well written and well illustrated. The amateur and the expert are both served equally well.—W. Z. HUTCHINSON, editor and proprietor of the *Bee-Keepers' Review*, and author of *Advanced Bee Culture*.

No bee-keeper's library can be at all complete without a copy of this magnificent apiarian work. It has reached a sale of over 100,000 copies already, being the most largely sold book on bees in the world. Better send to us for a copy to read during the long winter evenings.—*American Bee Journal*.

This work of 536 pages is, as its name implies, a complete cyclopædia of everything pertaining to bees and bee-keeping. It was originally compiled by A. I. Root, who in the 1877 preface, after stating his indebtedness to Langstroth, Quinby, and others, says that "A great part of this A B C book is really the work of the people, and the task that devolves on me is to collect, condense, verify, and utilize what has been scattered through thousands of letters for years past." Since the first copy of this work appeared, now thirty-one years ago, it has undergone many revisions, and has had many additions, both of letterpress and illustrations, while the rapid advancement in bee culture has made it necessary in many cases to remove whole articles and rewrite them entirely. The revision has been ably carried out by E. R. Root, the present editor of *GLEANINGS*, who has had the assistance of a number of well-known and able men. In the preface the names of the writers of the different articles are given. For instance, we find Dr. C. C. Miller writes on honey-comb and out-apiaries; Dr. E. F. Phillips on the eye, parthenogenesis, and scent of bees; E. R. and H. H. Root on wax and wintering, both of these having carried out a number of experiments on these subjects. There are also articles by W. K. Morrison and Mrs. Comstock. It seems almost superfluous to say any thing about a book of which already 100,000 copies have been sold; the simple fact speaks for itself that it fills a want, and is an attestation of its worth. Among the articles that have been revised we find the new methods of queen-rearing described, so that the practical bee-keeper will have the latest and best ideas on the subject before him for reference. The new methods of wax-production are treated in an exhaustive manner; and as this subject is of more importance than formerly, greater space has been devoted to it. We have nothing but good words for this work, and recommend our readers to get a copy of the 1908 edition. The work is profusely illustrated and beautifully printed, and is a credit to the publishers.—By T. W. COWAN, Esq., editor of the *British Bee Journal*. Mr. Cowan is the author of two first-class books on bees and bee-keeping, "The Bee-keeper's Guide" and "The Honey-bee."

## Honey Markets.

The prices listed below are intended to represent, as nearly as possible, the average market prices at which honey and beeswax are selling at the time of the report in the city mentioned. Unless otherwise stated, this is the price at which sales are being made by commission merchants or by producers direct to the retail merchant. When sales are made by commission merchants, the usual commission (from five to ten per cent), cartage, and freight will be deducted, and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage, and other charges, are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

### EASTERN GRADING-RULES FOR COMB HONEY.

**FANCY.**—All sections well filled, combs straight, firmly attached to all four sides, the combs unsoiled by travel-stain or otherwise; all the cells sealed except an occasional one, the outside surface of the wood well scraped of propolis.

**A No. 1.**—All sections well filled except the row of cells next to the wood; combs straight; one-eighth part of comb surface soiled, or the entire surface slightly soiled; the outside surface of the wood well scraped of propolis.

**No. 1.**—All sections well filled except the row of cells next to the wood; combs comparatively even; one-eighth part of comb surface soiled, or the entire surface slightly soiled.

**No. 2.**—Three-fourths of the total surface must be filled and sealed.

**No. 3.**—Must weigh at least half as much as a full-weight section.

In addition to this the honey is to be classified according to color, using the terms white, amber, and dark; that is, there will be "Fancy White," "No. 1 Dark," etc.

### NEW COMB-HONEY GRADING-RULES ADOPTED BY THE COLORADO STATE BEE-KEEPERS' ASSOCIATION.

**No. 1 WHITE.**—Sections to be well filled and evenly capped except the outside row, next to the wood; honey white or slightly amber, comb and cappings white, and not projecting beyond the wood; wood to be well cleaned; cases of separator honey to average 21 pounds net per case of 24 sections, no section in this grade to weigh less than 13½ ounces.

Cases of half-separated honey to average not less than 22 pounds net per case of 24 sections.

Cases of unseparated honey to average not less than 23 pounds net per case of 24 sections.

**No. 1 LIGHT AMBER.**—Sections to be well filled and evenly capped, except the outside row, next to the wood; honey white or light amber; comb and cappings from white to off color, but not dark; comb not projecting beyond the wood; wood to be well cleaned.

Cases of separator honey to average 21 pounds net per case of 24 sections; no section in this grade to weigh less than 13½ ounces.

Cases of half-separated honey to average not less than 22 pounds net per case of 24 sections.

Cases of unseparated honey to average not less than 23 pounds net per case of 24 sections.

**No. 2.**—This includes all white honey, and amber honey not included in the above grades; sections to be fairly well filled and capped, no more than 25 uncapped cells, exclusive of outside row, permitted in this grade; wood to be well cleaned, no section in this grade to weigh less than 12 ounces.

Cases of separator honey to average not less than 19 pounds net.

Cases of half-separated honey to average not less than 20 lbs. net per case of 24 sections.

Cases of unseparated honey to average not less than 21 lbs. net per case of 24 sections.

**CINCINNATI.**—The market on comb honey is very slow; some new goods have arrived, but there is no demand, and it is selling slow at 14. There is some new white-clover extracted honey coming in, selling at 7½. Amber in barrels is selling at 6 and 6½. Beeswax is selling at \$33.00 per 100 lbs.

June 22. C. H. W. WEBER, Cincinnati, O.

**SAN FRANCISCO.**—It appears now as though there would be a very short crop in the West this season. The season for honey-making was much delayed by the cool weather, and so far very little of the new crop has arrived. The feeling of the market on these reports is very firm, and the prices are expected to advance rather than drop. Water-white comb, 16 to 17; white, 15; water-white, extracted, 8 to 8½; light amber, extracted, 7 to 7½; dark amber and candied, 5½ to 5¾.

June 20.

Pacific Rural Press.

**NEW YORK.**—Comb honey: The demand is next to nothing, and has been so for the past four months. A few crates of fancy No. 1 white are called for once in a while, while off grades and dark are entirely neglected. As there is practically no demand, quotations are simply nominal. We have more in stock than we can dispose of. The honey will have to be carried over until next fall. We can not encourage shipments of comb honey, as we do not think we shall be in position to render account of sales within reasonable time. Extracted honey: Demand better and market slightly improving. New crop is arriving quite freely from the South, where the yield seems to have been pretty large. We quote California white sage at 8½ to 9; light amber, 7½ to 8; amber, 6 to 6½; new crop Southern from 58 to 75 per gallon, according to quality. West India honey is arriving in fairly good-size lots and finds ready sale at from 60 to 62 per gallon, duty paid. Beeswax in good demand, and firm at 30 to 31.

June 4.

HILDRETH & SEGELKEN,  
265-7 Greenwich St., New York.

**CINCINNATI.**—The demand for comb honey has fallen off considerably in the past twelve months. Last year the comb-honey market was bare in February, but this season finds an abundance of that article everywhere at this date, which is late for last season's crop. We can not tell at present what effect this state of affairs will have upon the market when the new honey comes in. The market on extracted honey shows some life, but is not moving rapidly. Quote amber in barrels at 6 to 6½, according to the quality; fancy extracted honey, 7½ to 9. For choice yellow beeswax, free from dirt, we are now paying 28 cts. cash and 30 in trade, delivered here.

June 15.

THE FRED W. MUTH CO., Cincinnati, O.

**PHILADELPHIA.**—The prospects at present are for one of the largest crops of honey we have seen in the East for the last ten years. The result is, prices are uneasy and have a strong downward tendency. Some few little lots of comb honey are being offered, but not enough to establish a price. We are looking for very low prices the coming season. Beeswax is firm at 28.

June 22.

WM. A. SELSER, Philadelphia, Pa.

**INDIANAPOLIS.**—With the exceptions of a few lots of old comb honey the local market is practically bare of honey. Dealers are awaiting arrival of new crop, but as yet no prices are established. Beeswax brings 28 cents cash or 30 in exchange for merchandise.

June 16.

WALTER S. POWDER,  
Indianapolis, Ind.

**BOSTON.**—Fancy white comb honey, 17; No. 1 white comb, 16; California white sage, extracted, 9; California light amber, 8; Southern honey in barrels, slow sale, 5 to 6.

June 12.

BLAKE-LEE CO., Boston, Mass.

**DENVER.**—Our market is now entirely cleaned up of comb honey, and the first consignments of the new crop should find a ready sale at good figures. We quote extracted white, 8 to 9; light amber and strained, 6¾ to 7½. We pay 25 cents per pound for clean yellow wax delivered here.

June 15.

THE COLORADO HONEY-PRODUCERS' ASS'N,  
F. RAUCHFUSS, Mgr., Denver, Colo.

**LIVERPOOL.**—The market for honey and beeswax is steady and quiet. We quote honey, Chilean, 4 to 6½ cents; Peruvian, 3½ to 5½; California, 7½ to 9; Jamaican, 4 to 5½; Haiti, 6½ to 6¾. Beeswax is very firm—African, 30 to 32; American, 30 to 33; West Indian, 29 to 32; Chilean, 30 to 36; Jamaican, 34 to 35.

June 16.

TAYLOR & CO.,  
7 Tithebaron St., Liverpool.

**ST. LOUIS.**—The honey market is very quiet. There is absolutely no demand for comb honey. Extracted honey is also neglected, consequently the prices have declined. Quote as follows: Fancy white comb honey, 15 to 16; No. 1, white and amber, 12 to 14; broken and defective, less. Extracted white, in cans, nominal at 8 to 8½; amber, 7 to 7½; in barrels, 5½ to 6; granulated extracted honey sells at less. Beeswax, 29 for prime; impure and inferior, less. R. HARTMANN PRODUCE CO.,

June 11.

St. Louis, Mo.

**ZANESVILLE.**—So light is the demand for honey at the present time that it is almost useless to quote the market. Stocks are pretty well reduced, and there is a tendency to cut prices, especially on the part of one-horse dealers. While the remnant of last year's crop is moving very slowly, some revival is anticipated with the arrival of the new crop. For good quality beeswax I offer 30 cts. in exchange for bee-supplies. Wax wholesales at 40 to 45.

June 18.

EDMUND W. PEIRCE,  
Zanesville, O.

# GLEANINGS IN BEE CULTURE

Established  
1873.  
Circulation  
32,000.  
72 pages.  
Semi-  
monthly.

Devoted to Bees, Honey, and Home Interests.

Published by THE A. I. ROOT CO., Medina, Ohio.  
J. T. CALVERT, Business Manager.

\$1 per year.  
When paid  
in advance:  
2 years, \$1.50.  
3 years, \$2.00.  
5 years, \$3.00.

POSTAGE IS PREPAID by the publishers for all subscriptions in the United States, Hawaiian Islands, Philippine Islands, Guam, Porto Rico, Tutuila, Samoa, Shanghai, Canal Zone, Cuba, and Mexico. Canadian postage is 30c per year. For all other countries in the Postal Union add 60 cents per year postage.

**CHANGE OF ADDRESS.** When a change of address is ordered, both the new and the old address must be given. The notice should be sent two weeks before the change is to take effect.

**DISCONTINUANCES.** The journal is sent until orders are received for its discontinuance. We give notice just before the subscription expires, and further notice if the first is not heeded. Any subscriber whose subscription has expired, wishing his journal discontinued, will please drop us a card at once; otherwise we shall assume that he wishes his journal continued, and will pay for it soon. Any one who does not like this plan may have it stopped after the time paid for it by making his request when ordering.

**HOW TO REMIT.** Remittances should be sent by Draft on New York, Express-order or Money-order, payable to order of The A. I. Root Company, Medina, Ohio. Currency should be sent by Registered Letter.

**AGENTS.** Representatives are wanted in every city and town in the country. A liberal commission will be paid to such as engage with us. References required.

## Foreign Subscription Agents.

Foreign subscribers can save time and annoyance by placing their orders for GLEANINGS with any of the following authorized agents, at the prices shown:

PARIS, FRANCE. E. BONDONNEAU, 142 Faubourg St. Denis. Per year, postpaid, 7½ fr.

GOODNA, QUEENSLAND. H. L. JONES. Any Australian subscriber can order of Mr. Jones. Per year, postpaid, 6/.

DUNEDIN, NEW ZEALAND. ALLIANCE BOX CO., 24 Castle St. Per year, postpaid, 6/.

## HOW TO KEEP BEES

The novice in bee-keeping usually seeks for a simple book on bees, and in this he is wise. The modern text-books relating to bees are excellent in their way, but most of them are too technical for a mere beginner,

however well they may be written. A simple book written in clear every-day language is much better, even if it does not treat of quite so many little details which interest only the professional bee-keeper. In this respect "How to Keep Bees" fills the bill. The gifted authoress, who is a charming writer as well as an artist-engraver and bee-keeper, made a start with bees three different times, hence she had the opportunity of finding out for herself the difficulties and trials that beset the beginner with bees. She had no desire to make money with bees, but did so, however, because they prospered under her care and skill. For this reason she writes as an amateur to amateurs, making no attempt to discuss the knotty problems which the expert bee-keeper is interested in. The book is written in a charming literary style, easily understood, almost entirely free from the technical language used by bee-keepers. It is arranged in chapters, and is so eminently readable withal that any one interested in the subject can sit down and devour it clear through, the same as he would a modern novel. Every thing the average beginner desires to know is discussed, including what to order if you have no bee-supplies or bees. The print is large, and some very beautiful engravings adorn its pages, for the authoress is one of the most skillful wood-engravers in America. We can not do better than recommend this work to every beginner in bee culture.

by Anna  
Botsford  
Comstock.

There are twenty chapters in the book as follows: 1. Why keep bees; 2. How to Begin Bee-keeping; 3. The Location and Arrangement of the Apiary; 4. The Inhabitants of the Hive; 5. The Industries of the Hive; 6. The Swarming of Bees; 7. How to Keep from Keeping too Many Bees; 8. The Hive and How to Handle It; 9. Details Concerning Honey; 10. Extracted Honey; 11. Points about Beeswax; 12. Feeding Bees; 13. How to Winter Bees; 14. Rearing and Introducing Queens; 15. Robbing in the Apiary; 16. The Enemies and Diseases of Bees; 17. The Anatomy of the Honey-bee; 18. Interrelation of Bees and Plants; 19. Bee-keepers and Bee-keeping; 20. Bee-hunting.

There is also a bibliography and index. From a beginner's standpoint it is a complete treatise on bees. Cloth bound (228 pages), price \$1.10 postpaid.

THE A. I. ROOT COMPANY, MEDINA, OHIO.

## T. B. TERRY'S HEALTH HINTS

published only in The Practical Farmer each week, have been the means of saving lives and thousands have been helped to enjoy life more than they have ever done before. Send **Twenty-five Cents** to The Practical Farmer, Philadelphia, Pa., and read Mr. Terry's Health Hints **thirteen weeks on trial**. You will be surprised to find how simple a matter it is to get well and strong and keep so. The latest and best that can be given you, together with strong editorials on Agriculture, Live Stock, Gardening, Home Life, etc. A high class weekly, well worth the subscription price of \$1.00 per year. Address

THE PRACTICAL FARMER  
P. O. Box 1317 PHILADELPHIA, PA.

## The Uhl Hatchery

Capacity 6000 chicks per week.

If you want 50 or 100 pure-bred chicks, write for our special low summer prices. We make the Brown and White Leghorns our specialty, and they are just the kind to raise during the summer. We hatch also several other varieties. Send for free catalog.

M. UHL & CO., Box C, NEW WASHINGTON, OHIO.

# And Still They Come

The following letter from one of our customers demonstrates in his own words the satisfaction our customers receive. Remember this is only one of the many thousands we receive.

Griggs Bros., Toledo, O.:—I received the hives and supplies to-day, which is the quickest I ever got goods after ordering. They must have come over in the Knaben shoe's airship. They certainly are in fine shape—utterly impossible for any thing to have got lost.

Your shipping-clerk had them packed to perfection.

Respectfully, HUGH RICHARDSON,  
Wood Co., O.

We should be pleased to list you as one of our customers if you are not one already. Bear in mind we handle ROOT'S GOODS exclusively, not the cheap shoddy stuff which others are trying to palm off under the pretense that it's "as good as ROOT'S." Try ROOT'S and you will be convinced. TOLEDO is the place to buy; we save our customers annually thousands of dollars in FREIGHT.

A complete line of Incubators and Poultry Supplies listed in our free catalog. Send for one.

Honey and Beeswax wanted in exchange for supplies.

## Special

200 cases of 60-lb. cans, good as new, at 50 cents per can. Special prices in quantities.

15 Cord Building, Indianapolis, Ind.

## THE DANZENBAKER SMOKER

PAT. OCT. 3, '08, JUNE 4, '07

**GOLD MEDALS**  
St. Louis Exposition, 1904  
Jamestown Exposition, 1907

IS THE BEST,  
STRONGEST,  
COOLEST,  
CLEANEST,  
CHEAPEST,  
AND LARGEST  
SMOKER SOLD  
FOR A DOLLAR

The perforated side grate seen above holds a removable, metal, asbestos-backed fire shell, preventing burning the tin off the outer case, and deflects the air at right angles, preventing back draft to the valveless bellows. The air, passing to the back and over the top, cools and expels the smoke, fanning the burning fuel at top or side till all consumed, giving cool smoke for hours from one filling. It can't clog. No top-heavy cap to choke with soot; no valve to fail; no holes shedding sparks or hot ashes.

Four years' sales prove its success beyond a doubt, expensive dies making it uniformly perfect as possible to devise. We confidently guarantee full satisfaction or refund the price.

Price, \$1.00; 3 for \$2.50; by mail, add 25c. each

Send address of yourself and Bee friends for 8-page leaflet on "Smoker," and facts about Bees and Queens, 80 pages, free.

**F. DANZENBAKER, Norfolk, Va.  
or Medina, O.**

Mr. T. S. Hall, Jasper, Ga., breeder of fine Italian queens, writes, June 11, 1908: "The three smokers came all O. K., and they are dandies; sure; are good smokers. We burn corn-cobs in them all right. We may send you orders for smokers, as several have expressed a desire for one."

Dr. R. Munson, Washington, D. C., says: "Your new smoker has a much stronger blast than the first one. I have been using the first one with a roll of newspaper, first starting the fire at the bottom, and it works finely that way, and stays lit all day. Firing it up at 8 A. M. and using it half an hour in my queen-rearing hives, and, setting it aside, I usually find it still smoking ready for use at 4 or 5 P. M."

## SACKETT WRAPPERS

(Transparent) FOR COMB HONEY

NOW BEING USED BY LARGE PRODUCERS

Makes section look more attractive, and increases selling price. Any one can apply it and get 2 to 4 cents more per pound, and it costs you only a fraction of a cent per section.

Price \$3.25 per thousand sheets,  
printed with name and address.

Samples free.

Special prices on quantities.

### SOMETHING NEW AND VALUABLE.

Producers of fancy comb honey will be greatly interested in the advertisement of Mr. Sackett, which appears elsewhere in these columns, wherein he calls attention to his new wrapper for enclosing sections of comb honey, thereby affording protection from dust, etc. The wrapper is made of transparent paper so that the honey is sufficiently seen by the customer before purchasing it. Instead of detracting from the appearance of section honey the paper really adds to it. It is, furthermore, quite a protection from drip, because, if a section leaks, the leakage is confined to that one section. The cost of these wrappers is small—more especially so when we consider their manifold advantages. We know Mr. Sackett, who is the inventor, will be delighted to correspond with prospective users of these wrappers, and would be glad to furnish necessary samples to all those who are interested in the production of comb honey of a superior grade.

### THE AMERICAN BEE JOURNAL.

We take great pleasure in giving a few words of commendation of the "old reliable" *American Bee Journal*, whose home is 118 West Jackson St., Chicago, Ill. As the mother journal of American bee papers, it is only right and proper that we should say a word in praise of our old friend. Recently it has taken on a new lease of life by reducing its subscription price to 50 cts a year, and becoming a monthly magazine instead of a weekly newspaper. Considering the low rate of subscription we can not see how a bee-keeper can afford to pass it by when making up his list of periodicals for the family library table. It has a strong corps of editors—men and women who are experts in the science of bee-keeping, and who know how to write interesting matter. As a further inducement to subscribe, the editor promises to give an untested queen to all those who send in their subscription now, at the rate of \$1.00 for the two. In other words, the paper is free.

The *American Bee Journal* has a record that carries it back into the misty past, when bee-keeping was in its infancy and there were only about three bee journals published in all the world, whereas there are more than eighty now. At the helm it has Mr. George W. York, who does all in his power to turn out a clean up-to-date bee magazine and thus sustain the best traditions of the "old reliable." We know he is always ready and willing to accept suggestions for the improvement of his journal; therefore the future policy of the paper lies largely with bee-keepers themselves. We therefore suggest that you remember the *American Bee Journal* when making up your list of papers for which you intend to subscribe.

### COLORADO INTERSTATE FAIR AND EXPOSITION.

DENVER, SEPTEMBER 7—12.

#### PREMIUM LIST OF THE APIARIAN DEPARTMENT.

Supt., W. L. Porter, 3522 Alcott St., Denver.

| No.  | CLASS NO. 59—BEES, HONEY, ETC.                                         |     |     |     |
|------|------------------------------------------------------------------------|-----|-----|-----|
| 984  | Italian bees and queen in single-comb observatory hive                 | \$5 | \$3 | \$2 |
| 985  | Carniolan bees and queen in single-comb observatory hive               | 5   | 3   | 2   |
| 986  | Caucasian bees and queen in single-comb observatory hive               | 5   | 3   | 2   |
| 987  | Largest and best display of bees of various races in observatory hives | 10  | 5   | 3   |
| 988  | Largest display of queens of various races in mailing-cages            | 3   | 2   | 1   |
| 989  | Best display, manipulation of bees                                     | 10  | 5   | 3   |
| 990  | Best case of white comb honey                                          | 3   | 2   | 1   |
| 991  | Best case of light-amber comb honey                                    | 3   | 2   | 1   |
| 992  | Best and largest display of comb honey                                 | 10  | 5   | 3   |
| 993  | Best display of special designs in comb honey                          | 3   | 2   | 1   |
| 994  | Best dozen jars of white extracted honey                               | 3   | 2   | 1   |
| 995  | Best dozen jars of light-amber extracted honey                         | 3   | 2   | 1   |
| 996  | Best and largest display of extracted honey                            | 3   | 2   | 1   |
| 997  | Best display of extracted honey in granulated form                     | 3   | 2   | 1   |
| 998  | Best 10 lbs. of yellow beeswax                                         | 3   | 2   | 1   |
| 999  | Best and largest display of beeswax                                    | 3   | 2   | 1   |
| 1000 | Best display of special designs in beeswax                             | 3   | 2   | 1   |
| 1001 | Best display of honey-producing plants in mounted form                 | 3   | 2   | 1   |
| 1002 | Best display of fruits preserved in honey                              | 3   | 2   | 1   |
| 1003 | Largest and most attractive display in department                      | 20  | 10  | 5   |

For entry-blanks, complete premium list and rules, or further information, call on or address G. C. Fuller, Acting Secretary, suite 416 Tabor Opera House Building, Denver, Col.

The following is the premium list in the apiarian department of the Indiana State Fair, to be held at Indianapolis, September 7—11:

| Sec. | 1                                                                                       | 2    | 3        |
|------|-----------------------------------------------------------------------------------------|------|----------|
| 1522 | Display of comb honey—quality, quantity, and manner of putting up for market considered | \$25 | \$15 \$8 |

|      |                                                                                                                 |    |    |   |
|------|-----------------------------------------------------------------------------------------------------------------|----|----|---|
| 5123 | Display of extracted honey—quality, quantity, and manner of putting up for market considered                    | 25 | 15 | 8 |
| 1524 | Display of beeswax, quantity and quality to be considered                                                       | 10 | 8  | 6 |
| 1525 | Honey vinegar, not less than one gallon, in glass                                                               | 5  | 3  | 2 |
| 1526 | One-frame observatory hive of Italian bees, showing queen, workers, and brood in all stages                     | 10 | 8  | 6 |
| 1527 | One-frame observatory hive of foreign bees, other than Italian, showing queen, workers, and brood in all stages | 10 | 8  | 6 |
| 1528 | Display of bee-supplies                                                                                         | 20 | 10 | 5 |
| 1529 | Best general display of honey, wax, supplies, and other material pertaining to the bee industry                 | 20 | 10 | 5 |

The above sketch shows Mr. Oliver Harris, hauling a load of hay across his marshy meadow. He writes The Electric Wheel Co., Quincy, Ill., that this is the first load of hay ever hauled over this meadow in April as he could never get through the mud with his high wheel, narrow tired wagons. With a low wheel, wide tired Handy Wagon such as The Electric Wheel Co. make, he finds it an easy job and claims he saves \$23.00, the price of this wagon, in horse-flesh alone, every year.

Our readers with muddy meadows or soft roads will be interested in a catalogue of these wagons which the above company sends free for the asking.

# RASPBERRY HONEY

Our bees in Northern Michigan are storing raspberry honey. At this writing, June 19, some colonies have on their second super, and by the time this issue of GLEANINGS reaches its readers it is likely that some colonies will have on three supers. By the time another number of GLEANINGS is sent out we shall probably be extracting.

Heretofore we have never offered the honey for sale until it was actually in the cans and stored at the railroad station. This causes a delay. Sometimes the honey has been extracted a month before we get orders for it. It would be an advantage to us and to buyers if we could have orders in advance. Then we should not have to go to the trouble and expense of storing it, but

could ship it at once as soon as off the hives, while customers would get their honey that much earlier in the season. If any one cares to send us advance orders, such orders will be greatly appreciated, and the honey will be shipped the very day that it goes into the cans.

The honey will be put up in bright *new* 60-pound tin cans, two cans in a case, and the price is ten cents a pound, or \$12.00 for a case of two cans. Remember, this is wild-red-raspberry honey, and will not be extracted until all sealed over and thoroughly ripened, and will be thick, rich, and delicious.

**W. Z. HUTCHINSON, Flint, Mich.**

## LISTEN!

## DO YOU HEAR THOSE BEES WORKING?

Soon they will want room or will swarm.

Have you gotten your hives and supplies? If not, send your order at once. If you have The A. I. Root Co.'s catalog you can order from it. We sell their goods at their factory prices. We can fill your orders promptly now. Write for further information and our 40-page catalog.

**JOHN NEBEL & SON SUPPLY CO., HIGH HILL. MONTG CO., MISSOURI.**

# BEE KEEPING

will be a profitable industry this season.

Honey is high—short crop last year. The shortage of the honey crop for 1907 in the United States warrants bee-keepers to increase their colonies. About a half crop was produced, and in California, where the cheap honey comes from, only a quarter of the average crop was produced.

## Get Ready Now for More Honey

Let us send you our catalog. We are manufacturers and sell only our own make of bee-supplies. Minneapolis is the largest lumber-distributing point; the Mississippi river furnishes us power, and our organization and labor conditions are the best for economical production. Send us an estimate of your requirements and let us give you prices. We have a large stock of standard bee-supplies on hand.

Dovetailed Hives, Sections, Section-holders, Separators, Brood-frames, Comb Foundation, Smokers, Extractors, Shipping-cases, etc.

**MINNESOTA BEE SUPPLY COMPANY, 23 Nicollet Island, Minneapolis, Minn.**

## TO THE BEE-KEEPERS of CANADA.

WE are pleased to say that we are able to offer, in Canada, goods manufactured by The A. I. Root Co. While we do not offer every thing listed in their catalog, we have selected such articles as we believe will best meet the wants of the Canadian bee-keepers.

The heavy duty and freight charges we have to pay make it impossible for us to sell in Canada at Root's prices. We have, however, made prices as low as possible, and in no case do we charge nearly as much extra as the amount of freight and duty we ourselves have to pay on the goods.

We would ask you, when comparing our prices with those of other dealers, to take into consideration the QUALITY. If you do so we feel satisfied that you will place your order with us. The splendid quality of the material sent out by The A. I. Root Co. has given "Root's Goods" a world-wide reputation. Remember, "The best is cheapest."

A NEW HIVE-TOOL

Hitherto we have said very little about our new hive-tool, but after submitting it to some of the foremost bee-keepers of America for their candid opinion—for or against—the universal verdict is that it is a good thing; though it looks like a very simple tool it is very surprising how useful it is to an apiarist. The bent end, for example, is just right for severing Hoffman frames. A slight twist of the wrist does the business without angering the bees, and one's hand is so placed the bees do not see it. For scraping wax and propolis nothing could be finer, and it is better than a chisel, screwdriver, or putty-knife for opening hives. Any bee-keeper will be glad of one in his pocket ready for all occasions. It is made of the finest hardened steel nickel plated.

Sample Testimonial:

Mr. Root:—I have been using your nickel-steel hive-tool this spring, and am very much pleased with it. It is the best thing I have tried yet. I, with my helper, have been using tack-pullers heretofore; but this is better because so much stronger. It leaves nothing to be desired except that there should be a hole in it a little nearer the crooked end. I tried to get one drilled but had to give it up—too hard; so I fastened a strap around it to fasten to my pants button.

Oberlin, Ohio.

A LITTLE KNOWLEDGE OF THE BEE BUSINESS

By the Bee Crank:

A certain young lady who was visiting in the country sat down to the dinner-table, which was loaded with all the good things that are found on the farm. With the other good things she noticed a dish of honey, and she exclaimed, "Ah! I see you keep a bee."

Of course this was an extreme case, yet many bee-men are but little better posted than the young lady mentioned. The successful bee-man, like the modern farmer, is the one who uses his brain as well as brawn, and who leaves no stone unturned in gaining knowledge of his specialty. It seems to me that no other agricultural industry has developed the improvements and conveniences that are now at the command of the bee-keeper. The bee-man who can get along with "a good enough out-

fit" usually hangs on instead of pushing on.

I do not believe you can afford to use goods inferior to these which I am shipping all over this great country. I notice that the demand for the Danzenbaker hive is on the increase, and rapidly too. Sections, smokers, and every thing used in the bee-yard, here and ready

for you. My Catalog is free.

Save your beeswax for me and send it here and secure highest market price, cash or in exchange for goods.

Hoosier-Italian queens are being sent by immediate return mail. If the world is producing any thing better, I do not know it. Gentle, beautiful, and hustlers. Select untested, \$1.00; untested, 75 cents, or six at one mailing at 65 cents each.

Walter S. Pouder,

STRAY STRAWS

DR. C. C. MILLER

NORTH CAROLINA is the latest addition to the list of prohibition States. Next!

ALL BEES disappear at 65° north latitude, *except bumble-bees*. So when bees are reported in arctic regions proper they must be bumble-bees.—DR. V. BUTTEL, *Bienen-züchter*, 50.

J. A. CRANE gives a good plan for starting nuclei, p. 757. But instead of caging the queen three days would he not be more sure to get cells started, and to get more of them, if he removed the queen entirely for three days?

REFERRING to a Straw on page 411, A says he didn't want his money back because the queen died several months after introduction, but on account of the poor stock he got. Perhaps I got cases mixed.

"SMOKING is not allowed during office hours." That's one of the latest rules issued by the Rock Island R. R. [Good rule, and it ought to apply to all business offices in the land, especially if women are in the room.—ED.]

THANKS, Bro. Crane, for your tender consideration of my feelings, p. 747; but haven't I always advised beginners to begin with such sections and separators and bees as will give solid combs? And I've never been able to get such sections as well without the two pieces of foundation as with.

MEHRING, in 1857, made the first comb foundation, in a press with wooden molds. In 1874, Frederic Weiss, a German at Chicago, made the first foundation cylinders. Improved at Medina they are now used for nearly all the foundation made in this country. Weiss died in the poor-house at Chicago. The fate of so many inventors!—*Ills. Monatsblätter*.

B. F. AVERILL says, page 756, "If bottom-bars are not of good thickness to support the weight of heavy combs, there is going to be sagging sooner or later." Is it not the top-bar instead of the bottom-bar that supports a heavy comb? and if the top-bar does not sag, will the comb sag, even if there is no bottom-bar at all? Mr. Averill has struck the right thing in putting horizontal wires closer at the top than bottom.

E. G. HAND, *Canadian B. J.*, p. 73, refers to a Straw, page 78, where I said a bee-moth with its head pulled off would lay an egg between the thumb and finger—perhaps several. He thinks I ought to have said "perhaps several dozen, and possibly several hundred." All right, friend Hand, I accept the "several dozen," if you or any

other good authority has proved it. "Several" is as far as I ever tried it, and I am skeptical about the "several dozen." Positively, however, I'll not accept the "several hundred," for that's more than a moth lays in her lifetime. Prof. Cook puts the total output at 100 or 200 eggs.

K. GUENTHER, *Leipz. Bztg.*, 79, says that in shipping bees the proper place to give ventilation is not at the top nor yet at the side nor front. In either of these cases the bees will crowd upon the wire cloth and shut out the air. He puts the wire cloth under, with strips, of course, to prevent shutting off the air. Thus prepared he sends swarms to all distances, even from Germany to America. [Mr. Guenther is right, according to our experience; but we go one better in the case of long-distance shipments, putting wire cloth on *top* and bottom. But in the case of weak colonies in a regular standard hive, and for moderate distances, wire cloth at the top is sufficient.—ED.]

ALUMINUM figures, indestructible, for numbering hives, are advertised in German journals, about two inches high, at $\frac{3}{4}$ cent each.—*Deutsche Bzcht.*, 17. Please let us know when they can be had at Medina. [These aluminum figures, when imported to America, with duty added, would come rather high. As it is, they are rather expensive, even in Germany; for most hives, where there is much numbering at all, would have three figures. This would cost $2\frac{1}{4}$ cents per hive. Figures printed on heavy tagboard manilla, boiled in paraffine, can be secured for very much less; and we have been informed that, when the material is boiled in paraffine, it holds its color and shape.—ED.]

A COLONY queenless for a time is sometimes stubborn about accepting a queen. Even after it has stung several queens, giving it one or two frames of brood will bring it to its senses.—*Leipz. Bztg.*, 77. [It is certainly true that a colony queenless for several days is very often stubborn about accepting an introduced queen. We have had that experience over and over again. The sooner one can introduce after the colony is queenless, the better. It has happened with us a great many times that, when cells are started, the bees seem to put their faith in the cells rather than in any foreign introduced interloper; but we never found that the giving of frames or brood, sealed or unsealed, helped the matter any. It has been our rule to let the bees have their own sweet will, making them build cells from choice larvæ.—ED.]

OCCASIONALLY bees may be seen loading up their pollen-baskets with wax from old combs. Dr. Brunnich, *Leipz. Bztg.*, 35, reports an especially interesting case. A bee was observed all day long for three days carrying loads of

beautiful white wax from a new comb lying on a board. To make sure it was the same bee, a dab of yellow paint was put on its thorax, and for fully eight days longer came the marked bee and carried its fifteen to twenty loads a day. [This is very interesting; but the trouble with the average American is that he is too much in haste for the dollars and cents to learn some of the hidden secrets of nature. This one bee referred to was making a specialty of gathering wax. It is a little strange that it did not bring others.—ED.]

LOUIS SCHOLL thinks the queen would not pass a dummy between brood-combs in the breeding season. Well, that's one of the things I've tried; and with one or more dummies between brood-combs (only one dummy in a place) the queen passes freely from one comb to another. As he says, a bad comb will stop her, but not a good dummy. [We have had just exactly your experience, doctor. A few days ago, in going through the south yard we found where the queen had gone behind the dummy to lay eggs, for we had placed one or two combs in the cool weather outside in order to make the breeding-room smaller to fit the small cluster; but the cluster had increased in size in the mean time, and the queen had occupied the comb the other side of the dummy, and with her a lot of bees.—ED.]

MRS. J. W. BACON, p. 693, speaking of caging a virgin queen for a few days in the nucleus before taking the laying queen away, says, "I find her dead nine times out of ten." I suppose that means she finds the virgin in the cage dead. I'm not sure it ever occurred here. How is it in Medina? And please tell us whether you still value the plan. [We suspect the trouble with Mrs. Bacon is that, in practicing the dual-introduction plan, she puts a second queen in too many days before the other queen is expected to lay; that is to say, No. 2 is too old at the time of getting out of the cage. Ordinarily we should say that the second queen should be given not more than three days before No. 1 lays. You ask what we think of the plan. While we made it work, we are not practicing it now, as we find we can get much better queens from cells put into a nucleus than from two or three or four day old virgins introduced to the same nucleus. The trouble is that the virgins are likely to receive rough treatment on being released, the degree of rough handling depending upon her age at the time of being let out from the cage. Years ago it was not deemed practicable to introduce virgins five or six days old. But they can be introduced very readily to baby nuclei, because these little weak stocks have less of a colony feeling, and will take up with conditions that they would not tolerate if they were stronger.—ED.]

"WOULD YOU advise me to try bee-keeping again? Stings affect me seriously. Some 18 years ago I gave up bee-keeping. Since then, but several years ago, I had three stings. One of the fingers swelled to the shoulder, and I carried the hand in a sling three days. Another on the face affected the side, numbing my arm, lasting about three days. The third, near left eye, closed that, and right eye partly, neck and shoulder swelling; was in fair health, but stronger now." Thus, in substance, writes L. R. Pen-

field. Hard to advise. If for the money alone, don't think of touching bees. If you like them so much that it's hard to let them alone, try it in conditions that will allow you to give them up any day with little loss. Avoid many stings at first by means of veil, gloves, and gentle bees, and it may be that, after a few stings, the effect will become less. If not, quit. [Mr. Penfield can overcome his difficulty easily if he will submit to a process of immunizing, such as we explained in GLEANINGS some time ago. Let him take a bee up by the wings, or get some one to do it for him; cause the bee barely to prick the skin of the hand or arm with its sting, then instantly brush it off. This should be done very quickly, so as not to get much of the poison into the wound. If no serious effect follows it may be repeated in about a week's time. After a month or two the dose may be repeated, a little oftener, say once in three days; but in each case care should be taken to get the smallest quantity of the poison through the skin. If this be repeated at intervals for a period of six months, the system will become gradually immunized to the effects of the poison, just as it does to other poisons; and in the same way increasing doses may be taken, and oftener. We had one case exactly similar to that of Mr. Penfield, in which the party can now go among the bees, and can be stung ten or a dozen times without any bad effects. One thing Mr. Penfield can not do; and that is, to take the whole of the effects of a sting. If it be left in the wound, and the entire contents of the poison-bag are injected into the flesh he will, of course, experience just the effects described; but if he presses the bee just hard enough against the flesh so that it barely pricks the skin, and no more, and *immediately* brushes it off, being sure not to press the poison-sac, the effect will not be serious; in fact, he may not notice it at all.—ED.]

EDITORIAL

MARKET early—or at least be sure that all honey is sold before the holidays.

WE have been using the Alexander wire-cloth bee-veil. With this, one does not have to use a hat; and in spite of the awkward looks of the thing it is decidedly comfortable. We really felt sorry for Mr. Alexander when we first saw him working in one of those head-gears. While it is not particularly pretty we can say of it, "Handsome is that handsome does."

MORE PURE-FOOD LAWS.

OKLAHOMA and Rhode Island have recently enacted pure-food laws for the protection of their citizens. The law in the first-named State is said to be quite stringent in its provisions, and requires the name of the producer or wholesaler on all goods. It may be well to remind our readers right here that they can render the inspectors considerable help by reporting cases of adulteration with reference to the sale of syrups and similar sweets. Laws of this kind require the co-operation of all good people to make them thoroughly effective.

W. K. M.

FOUL BROOD IN CENTRAL CALIFORNIA.

J. T. DUNN, County Bee Inspector, inspected apiaries on the west side, in the vicinity of Coalinga. Conditions among the honey-bees were not found to be the best. Forty-one apiaries were inspected, 2553 healthy colonies found, and 302 with foul brood. The inspection was one of the most thorough that apiarists on the west side have been subjected to.—*Fresno Republican*.

THAT INJURED EYE.

To the many inquiring friends who have expressed their regret and sympathy, we would state that the injured eye of which the editor spoke on page 683 is no worse; indeed, it is holding its own. We have begun to read proof again to some extent, and to read manuscript as before. But in the mean time we have been finding rest and recreation among the bees at the south yard. Possibly the reader has noticed that some of the editorial buzzings are fresh from the hive.

While the injured eye will never see perfectly again, yet it is of great assistance to the good eye in that it helps to relieve the strain on the other member.

TIERING UP UNDER OR OVER.

The question often arises whether to tier up during the height of the honey-flow by putting an empty super *under* the one partly filled, or whether to place supers in the reverse order. This year at our out-yards the first set of supers were filled full or nearly full from alsike alone, and the flow is now only half over. White clover is just coming in, with basswood to follow. We therefore place all the empties under those partly filled. The effect in every case has been to check swarming, and inspire new energy in the bees, as these two portions of the hive must be connected with honey. A little later we shall place the empties on top.

POISONOUS HONEY WANTED.

PROF. H. A. SURFACE, Economic Zoologist of the Department of Agriculture, Harrisburg, Pa., so well known to our readers as a zoologist and enthusiastic bee-keeper, is desirous of receiving samples of honey supposed to be made from the laurel in the southern part of this country, and from the loco weed of Arizona, or any poisonous plants supposed to yield nectar or honey that poisons either human beings or the bees themselves. He is conducting an investigation, and we hope our readers in possession of any poisonous honey will send through the mails a good-sized package of it, which he will examine. Send also a few hundred dead bees that are alleged to have died from the effects of the poison.

THE PRODUCTION OF COMB AND EXTRACTED HONEY IN THE SAME HIVE A MEANS FOR THE PREVENTION OF SWARMING.

WE are satisfied that swarming can be allayed and checked to a great extent, even in the production of comb honey, if the brood-nest is never allowed to become very much crowded. There is no harm in putting the super on a few days ahead of time—better by far than one day too late, resulting in the bees hanging out and the starting of initial swarming-cells. That is the

beginning of the swarming fever, and after that it is almost impossible to break it up; but if one is forehanded enough to be a little premature in putting on supers and giving large entrances (whereby the bees are less inclined to lie out in front), it will go a long way in checking the swarming nuisance, especially if the honey-flow is good.

BERLEPSCH, DZIERZON, AND HUBER, AND THE INVENTION OF MOVABLE FRAMES.

DR. BRUNNICH, who writes so entertainingly of bees and bee-keeping in another part of this journal, takes issue with me in respect to the position of Berlepsch in the history of bee-keeping. Any reader of GLEANINGS who read my article on bee-hives in the issue for May 1 can not help coming to the conclusion that Dzierzon did not invent movable combs, neither did Berlepsch invent movable frames. Both inventions were known (*and used*) before either of these famous men was born. Huber, the Swiss, is the undisputed inventor of movable frames. He also discovered the main facts connected with the theory of parthenogenesis. Our German bee-keeping friends could do nothing better than to cut loose from their present system and adopt the Langstroth frame and hive just as the French and English have done. One of those same Texans can look after 500 colonies as easily as anybody in Europe can look after 100 Berlepsch hives. At least, that is our opinion on this side of the herding-pond, and quite a number of other nations are following us.

W. K. M.

FREE HOMESTEADS.

IN Northern Wyoming, 75 miles east of the Yellowstone National Park, 300 farms, from 40 to 160 acres each, have been thrown open for entry under the terms of the Reclamation Act. This tract embraces about 15,000 acres, constituting the first unit of the great Shoshone irrigation project. The charge for water rights has been fixed at \$45.00 per acre, payable in ten annual installments; but the second installment of \$5.50 does not become due until the fall of 1909, so that the settler can secure two crops before that time. The extra dollar is for maintenance—that is, to keep the dam and ditches in good repair. Actually, the settler pays nothing for the land, only for his share of the dam, etc., in which he is a shareholder. The land and the water are inseparable. At present the only way to reach these lands is over the Chicago, Burlington & Quincy Railway; but a north and south trunk line is in course of construction, connecting Billings, Montana, with Denver. It is estimated that a settler ought to have at least \$1000 to make a fair start. It is almost unnecessary to add that this will be a fine bee range just as soon as the settlers get their alfalfa started. The climate is unexcelled. Bees may be wintered out of doors, with a fair amount of protection. Employment may be obtained from the Reclamation Service in digging canals and other work, and homesteaders will have the preference. The project is being extended so that there will be work for several years yet in extending the present systems of canals. Further information may be obtained by addressing the "Statistician," United States Reclamation Service, Washington, D. C.

W. K. M.

STARTING STUBBORN COLONIES UP INTO THE SUPERS.

WE advocate (and always have), giving a shallow extracting super to a colony backward in going into the sections. After it begins on this a little, we take it away and give it sections. In the case of a *particularly* stubborn colony we practice giving an extracting-super from another hive in which the bees are nicely started in *building comb* and *storing honey*. This is kept on for three or four days, after which we give it to another stubborn colony.

These shallow extracting-supers that the bees have begun to work in are splendid to coax the bees upward. When the honey crop has been secured, one will have both comb and extracted honey. The proportion of either can be regulated to suit the local demand.

A PAINLESS STING.

WE had a strange experience yesterday, June 23, and we desire to know whether anybody else has ever had anything like it. We were stung on the wrist about one inch above the palm of the hand, at a point where, ordinarily, it would be very painful; but, strange to relate, there was absolutely no pain. The bee had lodged its sting so well that it had difficulty in freeing itself. As a matter of fact, we did not discover that we had been stung until we saw the bee whirling around and around in the effort to free itself. We removed the sting, located the small puncture, but there was no blister or swelling, *and no pain*. It would look as if one bee, at least, had been possessed of all the parts of the sting save the poison. Has anybody else had the pleasure of receiving a painless sting in a tender spot where the skin is thin? We have had dozens and dozens of stings where the skin was thick and calloused, without feeling it, but never before at a tender spot.

PRICES OF HONEY THIS SEASON.

THE situation so far as California, Texas, and some other portions of our country are concerned, remains practically unchanged. In spite of premature reports to the contrary, we are satisfied that those sections will not yield a large amount of honey. California will have but very little, and the same is practically true of Texas. The market was demoralized in some sections by a good many left-over lots of Western comb honey which have now candied. If these had been sold before the holidays, when there was a crying demand for it, and when it could not be obtained for love nor money, the market would now be in a much better condition.

The indications for a fine flow in some of the Eastern States will have a tendency to lower prices a little from last year; but if the times pick up (as we confidently hope and expect them to do) the market will be nearly able to hold its own.

AN ALSIKE YEAR.

THE flow from clover in many sections of the rain belt seems to be exceptionally heavy; in fact, it appears to be one of the old-fashioned clover years of yesteryear. Some untoward weather conditions might cause it to stop short off; but this hardly seems probable at this date.

The high price of red-clover seed early this spring induced farmers to try alsike, which is an easy grower, and in connection with timothy it makes a very fine quality of hay. The experiment stations as well as farmers have been recommending it for dairy purposes. This fact, with the high price of red-clover seed, has resulted in a vast acreage of alsike this year. If the farmers would only test it carefully from the standpoint of milk and butter, and not from the standpoint of the tonnage of hay, they would probably be induced to grow it more largely in the future. If they do, localities ordinarily poor or fair will be made good for the bee-keeper.

Alsike comes on a little ahead of white clover, or at least it did so this season. As the former begins to wane, the latter fills up the gap and thus keeps up an uninterrupted flow; and then basswood, wherever there is any, nicely joins hands, so that this year especially many bee-keepers will have a continuous flow of from one month to six weeks.

But the clovers have not yielded as finely in every section. In parts of Minnesota, Iowa, Michigan, and New York, there has been too much cool weather and rain; but the recent hot spells must inevitably have changed the situation for the better.

CAP-MELTING APPARATUS AND ITS PATENTABILITY.

IN our issue for May 15, page 626, and also for May 1, page 560, we gave an opinion to the effect that the Beuhne patent, issued January 8, while narrow in its general claims, was broad enough to prevent any one else from covering the same principle. Since that time we have had a call from Mr. Beuhne, of Tooberac, Australia, and during the course of our interview with him we called attention to the weakness of his patent. As he appeared to be prior to any one else in the use of any and all methods for melting cappings as fast as they leave the knife, we suggested to him the possibility of securing a reissue of his patent, with broader claims. He consulted his patent attorney, and the latter has since informed us that he thinks it is entirely feasible; and then, moreover, he is of the opinion that his client can secure a broad patent on the *method or process*. For this Mr. Beuhne has filed his application. If this latter is granted it would bar any one else from securing a patent if he is not already barred by the patent of Jan. 8th last, and at the same time prevent any one from using the principle in any manner whatever, providing that such a one is unable to show that he used the method or process prior to July 10, 1907, the time that Mr. Beuhne filed his application. But Mr. Beuhne will not be disposed to be unjust or unfair to any inventor, providing any such inventor can give satisfactory proof of his use of the principle.

In this connection we may say that we have examined the Beuhne apparatus, and feel satisfied that it is a long way ahead of anything else that has so far been presented to the public. As he is a pioneer in the melting of cappings as fast as they leave the knife, he has tested almost every method that has thus far been presented, either in this country or abroad, and is prepared to show why the special construction that he uses is superior to any other design. Later on we hope to show drawings of his machine.

GLEANINGS FROM THE PACIFIC COAST

By PROF. A. J. COOK.

"Man proposes, but God disposes." How true of our honey harvest! I have always thought since coming here that California was in the lead as a honey-producing State. We get such phenomenal crops when the seasons are favorable that this might be the bee-keepers' paradise except for the too frequent off years. We thought till lately that we had only to reckon with the season's rainfall. We thought, as we would know of this in the early spring, we could know of a surety whether a golden harvest awaited us, and so we would not have to provide for fixtures unless a harvest was certain. With ten or twelve inches of rain in winter we were sure of a great harvest. With less rain we would not purchase supplies, and would arrange to busy ourselves in other ways than in working with our pets of the hive.

We now know that we reckoned without our host in this regard. I fear that we are behind our brother bee-keepers of the East. With good weather conditions for the season, they are quite sure of a crop. We must have abundant rainfall and a favoring season as well. For the past three seasons our rains have been abundant and timely, and we felt sure of a generous harvest. But our springs have been cold, and we have failed to realize our expectations. This works in three ways to knife expectancy: It keeps the bees from breeding in the months of February, March, and April; it hinders flight when the time of harvest comes, and it prevents the flowers from nectar secretion at the time of the regular harvest. I never knew a better season, so far as the rains go, than this, yet I fear that the harvest will be as light as that of two years ago. The weather is delightfully cool. I once heard a physician say that the time of which he was speaking was "distressingly healthy," so we may say here in California, this spring, that the weather is distressingly cool and delightful.

FRUIT-BLOOM HONEY.

We have just been eating a little honey that is almost surely pure citrus honey. I presume I might say orange honey; but as the lemons are also in bloom, and thickly planted close by the bees, it is quite likely from both orange and lemon. It is of delicious flavor, and we wish that we might have more of it. I had the good fortune in Michigan to secure, more than once, fruit-bloom honey. It, too, was very delicious. Of course, we can not usually get much of this honey, for, like the honey from soft maple and from the eucalypts here in California, it comes when there are but few bees, and so can never be important in the markets. It is of great value, however, in stimulating brood-rearing. The bees are also of equal or greater benefit in cross-pollinating the bloom and so in augmenting the crop.

A WORD REGARDING ANTS.

Ants are insects that most interest every beekeeper. They are of the same order as the bees,

the *Hymenoptera*; in development they approach nearest to bees; in habits and social instincts they are very much like the bees, and in brain development and functional differentiation they are strikingly like our honey-bees. They also interest us as enemies of bees. Indeed, in differentiation of function, and in intelligence, they are superior to our pets of the hive. Their habits of slave-making and habits of division of labor are wonderful indeed, and must challenge admiration from any that study their ways and habits.

We say of our bees that they are polymorphic, for they are of three forms; while most species of insects, and, indeed, of all animals, are of only two forms, the male and the female. Ants eclipse even bees in this respect. We not only find in the formicary (the nest of ants) the queen, the true female, whose sole function, in many cases, is to lay eggs; the male bees, the ants that are comparable to the drones of the hive, and the workers, which, unlike the others just mentioned, are wingless. But we find others with large jaws and heads that are often called soldiers. These do work to defend the home against intrusion. Again, in some species there are more than one kind of worker. These will be found of different sizes, and with difference in the development of several of their organs, like the mouth organs and other parts of the body.

There have been several theories advanced as to the cause of this polymorphism. I think the real cause is the one that is generally believed by the wisest and best informed of our bee-keepers. It seems that the same agencies that have worked in the evolution of different individuals in *Aphis mellifera* have also prevailed to modify the ants, the white ant, and the wasps. It seems certain that parthenogenesis, in all these cases, has differentiated the males from the females. The males come from eggs that have not been fecundated. This is also called agamic reproduction—that is, fecundation without males. It is strange that eggs can and do develop without receiving the male element, or sperm; but this is known to occur in other insects, like gall-flies and plant lice. In some cases the result of such development is a female and not a male. This is generally true of the *Aphids*. In the bees, wasps, ants, and white ants, it is, without doubt, true that the males come always from unfecundated eggs, and so are the fruit of parthenogenesis. We are greatly indebted to the great Dzierzon for the discovery of this great truth. The generally accepted theory, that the difference in the development of females, so that in some cases we get a true, perfectly developed female, the queen, and that in others we get the usually smaller workers, comes from difference in quantity and quality of food. That there is in case of bees qualitative difference as well as quantitative, is certainly true; but in case of wasps and ants this difference is often wholly quantitative; and so we may believe that the cause of variation of development is principally from difference in amount of food. A sort of starvation process causes a stay in the development of the ovaries. It is interesting that, in case of other organs, there is greater development in the workers than in the queen. We know that the tongue of the worker is longer; and that the pollen-basket, or corbicula, is not developed in the queen. There are tremendous puzzles to be

worked out in the matter of the evolution of these polymorphic forms, and the student of this subject has great prospects before him. Darwin, Spencer, and Weismann all attacked the problem, and gave us much that is helpful; but there is a vast deal to be discovered even yet; and the one who comes to the subject with the time and ability to discover the ways that God works out these changes will be, like the great Dzierzon, a benefactor.

Claremont, Cal.

CONVERSATIONS WITH DOOLITTLE

UTILIZING THE CELLS IN COLONIES THAT ARE TRYING TO SUPERSEDE THEIR QUEENS.

"I had quite a little trouble last year in carrying out my plan of non-swarming, Mr. Doolittle."

"What seemed to be your trouble?"

"I bought quite a lot of queens during the summer of 1906, and for some reason these queens seemed to have hard work to keep up the strength of the colony. Some of the colonies having these queens increased in bees very little after they were set from the cellar, and some died outright. Many colonies would build supersedure cells, and, although not very full of bees, quite a few of them would swarm on these cells unless prevented."

"About what time of the year was this?"

"Along the latter part of May and the fore part of June; and, although not by any means as strong in bees as those colonies mothered by queens of my own raising, quite a per cent would swarm on these cells."

"Did any of your own stock act in this manner?"

"None, only some of my very old queens. I had two of my best old queens which did the same, but one was three years old and the other four. I had started in to control swarming, and every queen that seemed able to do reasonable service till the flow should come was retained and the cells cut out. To do this I handled over the brood-combs of the entire apiary, once every ten days to two weeks, and it was a job I don't care to go through with again; and that is the reason I came over to have a talk with you. These colonies with those poor queens that I bought gave the poorest honey-yields of any."

"Why did you not requeen these colonies having the poor queens?"

"I thought it would be no better to requeen, because it was a hard time to rear queens; and, besides, to have those colonies rear young queens would get no more brood for the flow than just to keep the poor queens a while longer."

"It would look to me as if you were not thoroughly posted on the superseding-queen matter, because you go on and tell me how the bees reared cells to supersede those old queens, and swarmed with those cells, or the queens from them, I suppose you meant; and then you tell me that you kept all of those old queens that you thought would possibly do any thing, because it was a hard time to rear queens. You further said to

have let these colonies rear young queens would get no more brood for the flow than to keep just the old queens a while longer, and so you just worked and worked, cutting cells to keep down supersedure swarming."

"What else could I have done?"

"Let me tell you that the queens which emerged from those supersedure cells were as good as any queens you ever had."

"What? Do you call queens good reared from those miserable queens which I bought?"

"But you said that two of your best old breeders did the same things, and the cells from these were as good as any you ever had from those queens during the years before, and it was *not* a hard time to rear queens, for the bees reared them themselves, without any hard work on your part at all."

"But I thought the honey harvest must be on in order to rear good queens."

"That may be so where the novice is rearing forced queens; but with the bees superseding queens of their own accord during the latter part of May and the fore part of June, they are making no mistake, I assure you, as to the quality of the queens they raise. You should have taken every cell you could from these two colonies with your old breeders, and, after cutting out all the cells from other colonies, put one in each colony which was found trying to supersede its queen. You would thus have superseded all of those poor queens without any swarming, without cutting of cells, and without *expense* of brood-rearing, and done the whole at one stroke; for the old queens would have kept right on laying just the same for all the cell or the young queen emerging therefrom, till she got ready to die, so you would have had all the brood you could have had in any other way till this young queen began to lay, when she would have boomed the brood without much danger of any swarming during the whole season."

"That does look reasonable, as you tell it."

"Yes, and it is reasonable in practice, as well. This is as I manage with supersedure cells early in the season, when I find any of my best colonies trying to supersede their queens, and I find there is no work in the apiary pays better than thus saving all supersedure cells."

"But if other colonies are not known to have supersedure cells, how can you use such?"

"The record kept of the age of queens, and other records, show which are my oldest as well as poorest queens; and if none of these colonies are found to have supersedure cells started, the nearly ripe cells I may have from my good old breeder, or from any good stock which is trying to supersede its queen, are put in these colonies which I think may try to supersede their queen a little later on, and in this way I nip the thing in the bud, and have many colonies renew their queens without any expense save the insertion of one of these nearly mature cells."

"Do you leave any cell with your best queen which is being superseded?"

"No, not until I see she is about to give out entirely; for if I did, as soon as the young queen emerged therefrom that would stop any further building of cells from this source. I always consider myself very fortunate when I find any colony of real good stock trying to supersede their

queen at any time during the months of May, June, July, or August, for then I cut out all the cells every ten days and use them. If I do not have colonies which will accept them, as I have just told you, I form nuclei to take them, and, when laying, later on, after the main honey harvest is past, I supersede all queens, which do not come up to my standard of perfection, with these which are ready to be used at any time, and in any place I may wish. I fear bee-keepers in general do not fully realize the value of this superseding matter as they should."

Borodino, N. Y.

GENERAL CORRESPONDENCE

THE NATIONAL BEE-KEEPERS' CONVENTION.

Of What Should the Program Consist?

BY DR. C. C. MILLER.

The article published in the *Bee-keepers' Review* by Secretary Hutchinson, as a sort of prospectus of the coming National convention, shows a careful consideration of some of the things that go to make up a good convention. Not only because of its bearing upon the coming National convention, but much more because of its bearing upon bee conventions in general, it is worth while to give the matter further consideration. Indeed, so important is it that, for the sake of emphasis, some of Secretary Hutchinson's points may be repeated, even if nothing is to be added to or subtracted from them. Moreover, it would be a good thing if members would take Secretary Hutchinson at his word, and give "help, hints, and suggestions" that may make the convention "vastly better." Like other things connected with bee-keeping, there is room for constant improvement in conventions, and worse use might be made of space in bee papers than in discussing the topic.

The discussion of some special topic for the first evening, or, for that matter, at any session, with stereopticon views is good. The only trouble is that it may not be practicable to have the stereopticon at all the smaller conventions. But that detracts nothing from its value wherever and whenever practicable.

Mr. Hutchinson suggests, as a thing never before attempted at a National convention, to have "at least one debate during each of the day sessions." Put in that general form, it is certainly nothing new, for more than one lively debate has occurred in many a session. But Mr. Hutchinson explains that he means something a little different—a regular pitting of two debaters against each other, prearranged, each an able defender, the two holding opposing views. That might be a good thing. Again, it might not. If a convention is made up of members who are slow to take part in the discussion of topics presented by the question-box, then it would help to have the time partly occupied as indicated. But if the time for formal debate is to crowd out impromptu

debate—for almost any topic offered in the question-box is pretty sure to awaken discussion with opposing views—then it might not be a good thing. Mr. Hutchinson says that "we common folks can sit back and enjoy the 'flow of words and the feast of reason.'" Couldn't we enjoy the same thing just as well in our own homes by having the two speeches printed in the bee journals? Indeed, that's just what we do have in the bee journals, frequently and constantly. But the vim and the snap of the impromptu discussions, when many an idea is brought out that would not be presented in a prearranged debate, nor given in the bee journals, partly because some will take part in the offhand discussions who would not write for the journals the things they say in convention, these things we can not have except in convention, and we want to get there what we can not have elsewhere. In the days when more than now time was taken up in convention with prepared speeches or essays, one can recall that one gave scant attention to these many a time, thinking that one would get exactly the same thing to be read at leisure afterward, saving the attention for the wide-awake offhand discussions that could never be exactly reproduced on paper. Would it not be the same thing with any formal debate?

Most bee-keepers will heartily second Secretary Hutchinson's motion to cut out the banquet. The mass of bee-keepers are not nocturnal birds; and the banquet, with its late hours, would do more to unfit than to fit them for the next day's work. Whether all would favor an evening of prepared speeches, speakers not previously announced, is a question. But there is no disputing Mr. Hutchinson when he says: "To attend a convention at some distance from home is more or less of a strain, at best, and every precaution ought to be taken that the members should feel just as well and as bright as they possibly can; otherwise there is little enjoyment." There are breakers ahead in two opposite directions. There is danger that the long-continued strain of close attention may be so great that the sessions become a pain instead of a pleasure, and the tired mind may actually refuse to continue action. On the other hand, members feel they want to get in all the time they can in actual convention work—in real bee-talk. Well-meant but ill-directed kindness often suggests that something should be provided for the entertainment of members in attendance—an excursion by way of boat or trolley, etc. Some may enjoy this, but many will count it time lost. A mayor or other official, who doesn't know a drone from a worker, is chosen to make a welcoming address, enlarging upon the beauties of the place, its prosperous manufacturers, etc., and time is taken for a response, and this, too, will be counted time lost.

Well, if such things are not the best to provide proper relaxation, what is to be done to relieve the constant strain? It should be remembered that the strain comes, not from the number of sessions, but from the long-continued strain of each session. Plainly, relief should come by a rest in the middle of each session. In our public schools, instead of a continuous session from 9 A.M. till noon, a recess of 15 minutes is taken during the forenoon, and with that rest more is accomplished in the 2¾ hours left than would be

accomplished in the unbroken 3 hours. So let a recess of 15 or 20 minutes occur in each session. Have it distinctly on the program, so that by no possibility may it be omitted.

There is another matter of exceeding importance that helps to prevent the weariness of a long session—ventilation. In too many conventions there is no one whose special business it is to see to ventilation, and after the same air has been breathed over and over again for two to four hours it is no wonder that heads are not clear for close attention. Why not have a committee on ventilation? If there are not good means for constant ventilation, let all doors and windows be opened at recess, and let all arise from their seats and move about the room to avoid the chance of taking cold.

Marengo, Ill.

HOW FAR DO BEES FLY?

Some Evidence to Show that this Distance is Greater than that Commonly Reported.

BY J. J. WILDER.

I once lived in Arkansas, in a "point"—a small piece of woods extending out from woodland into a prairie. The forest was heavily timbered, and many of the oaks were hollow; and I have never seen in my famlings as many wild bees as were in this section. Bee-hunting and game-hunting were the sports of the day.

During the swarming season it was nearly an every-day occurrence to see or hear swarms passing over, going in various directions. I have seen some swarms go out across the prairie in such a direction that, if they did not change their course greatly, they could not have reached a destination under 25 or 30 miles, there being no trees in the direction they went. There was nothing but prairie grass, and occasionally a small island of sassafras-bushes which were often burned off by fire. Sometimes points of wood could be seen in the far distance, but these could not be reached without a great change in their course, and most of these points contained only small growth.

It was believed by some that the swarms going out on the prairie took up their abode in the prairie grass; but this was not proven, as no swarms of honey-bees could ever be found in it.

Peddling was a part of our business, with Little Rock as our market, and to reach it this prairie had to be crossed, and about midway there was an island of trees with a pool of water in it. We made this our stopping-place at noon or camping-place at night. Here we sometimes saw honey-bees on the bloom of hazel-nut bushes, and at first we thought there was a bee-tree there until we made diligent search for it, and found there was not. Then we concluded that the bees came from trees in the distant points, which were about ten or twelve miles away, even if it was in the point and not in woodland below it.

I have seen enough facts to lead me to believe that the black (wild) bees are far better travelers than the Italians, and that they never could have made the progress across the continent the black

bees have, and can never receive the same abuse at the hands of the inexperienced.

Cordele, Ga.

THE HONEY-GRADING RULES.

Too Many Grades Makes it Difficult to Distinguish One from the Other; a Plea for Simplicity.

BY L. C. CLARK.

The Eastern grading-rules for comb honey which head your market column are too complicated. There are too many grades for practical use. Here are three grades of honey, including No. 1; and it would puzzle an expert to designate the dividing line between these three grades. Why have any third-grade honey as described in your grading-rules? It would weigh from 7 to 9 lbs. per individual crate, and, taking your No. 2 as a basis, No. 3 might have only half of the surface capped over. It would not be any credit to a bee-keeper, nor would it pay him to ship or sell such honey in a retail way. It should be cut out and sold for chunk honey, or by weight in larger quantities, to the local trade. To make the matter more confusing to the novice you say in the last paragraph, "In addition to these grades it is to be classified (does this mean *graded*?) according to color—white, amber, and dark." Now, does this mean that each of the five grades named is to be divided into three more according to the three colors named? If this is intended it would make 15 grades, and no one could follow the rules with that number of grades. I realize that in some localities the honey might all be amber late in the fall, when it could be graded fancy amber, No. 1 amber, and No. 2 amber; but applying this rule to an entire crop of dark honey would give us fancy dark, No. 1 dark, and No. 2 dark. Who can imagine fancy dark honey or even No. 1 dark?

To simplify the rules I would suggest that A No. 1 grade be dropped entirely; for, according to the wording, there is very little difference between it and No. 1; and, for reasons before given, No. 3 should be dropped; also honey with any considerable part of the surface uncapped should be excluded from No. 2 or any other grade. This sanction of one-fourth uncapped in No. 2 and No. 3 is a temptation to some to send all kinds of unfinished leaky honey to market, to the detriment of the trade. Where is the trade that would take half-weight sections as specified in No. 3?

The rules of the Colorado Honey-producers' Association, page 490, are much simpler and more easily understood than the Eastern rules; and were it not for a class of amber honey there would be but two grades in these rules, which is enough except for the fancy trade of large cities. Bee-keepers may grade honey as they please, and it facilitates a fair understanding between the producer and commission men and dealers. But the retail buyer who is to consume the honey grades it with his eye before purchasing; and the color (white) is the most important consideration. Therefore it would seem that we should give color more prominence in our rules.

Bakersfield, Cal.

[The Eastern grading-rules were adopted at the convention of the National Bee-keepers' Association in Washington, in 1892. The matter had been thrashed out over and over again; but the rules that were adopted at that meeting, notwithstanding they did not please every one, have seemed to stand better than any thing else.]

It is very seldom that dark or amber *comb* honeys are marketed if we except buckwheat; and in referring to it we say "fancy buckwheat," "No. 1 buckwheat," etc. But when one has a certain lot of nice comb honey that is dark or amber, or of unknown source, or of a mixed source, the only way to mark and grade that honey is by the qualifying adjectives; as, for example, "fancy dark" or "No. 1 amber." There is so little of this honey produced in sections that a very small quantity, comparatively, of it is offered. Practically speaking, we do not hear of "fancy dark" or "fancy amber;" but it seems unavoidable to have these gradings to take care of certain lots of honey that must occasionally be offered.

The Western grading-rules apply to a strictly Western honey, nearly all of which is white with some amber. In the West, at least in the Colorado districts, the honey is graded in the matter of weights *by the case*, and we are of the opinion that it would be wise for the Eastern bee-keepers to adopt the same scheme in their grading-rules. It is simply impossible to make every section of a certain grade of the same weight; but it is possible to make all of the sections in a case average up.

This question is open for discussion, and possibly it may be wise to modify the Eastern rules to take in the scheme of grading by the case as well as by the section. This would be a very proper subject for the next meeting of the National Bee-keepers' Association to discuss at Detroit. The matter is respectfully referred to Secretary Hutchinson.

We must beg leave to differ with our correspondent wherein he believes that fewer grades would be desirable. They might be for one locality; but a set of grading-rules must be expansive enough to take in *all* localities, say east of the Mississippi River or west of it. The time was when there were fewer grading-rules, and trouble resulted from the fact that there was too great a difference between one grade and another. No, no! we feel sure that there should be as many grades as now exist. To go to the other extreme would only be going back to our old difficulty. —Ed.]

THE TROUBLES OF AN AMATEUR BEE-KEEPER.

Fall Fooling.

BY F. DUNDAS TODD.

"Leave well enough alone!" Not on your life, especially with such interesting possibilities as a hive of bees. I considered I had been dead lucky in landing up against trouble at the beginning of my bee-keeping career; and, having come well through my first campaign, I was ready to tackle something more difficult, just to keep myself interested. Happy thought! why not devote

one hive to experimenting with the Ferris double-queen system which was then being described in GLEANINGS?

It was now well on in September—far too late to start with this scheme; but I set to work to make the necessary fittings, got deeply interested and made them for all three hives, and sent for a couple of queens as a starter.

Problem: given a hive, find the queen. In the sweet springtime it is apt to be rather easy, for bees are few and queens are big; but it is difficult in September, when bees are many and queens are shrinking. I read all the matter in all the books and magazines on finding queens, and could tell the proper procedure with all possible complications. First, choose a sunny day and have the sun at your back; pick out the first frame and quickly glance over the next in the hive, then examine the one in your hand. Then take comb No. 2 and glance at No. 3, then examine the comb in your hand, and so on to the last frame. If unsuccessful, repeat. If still unsuccessful, stack the combs in pairs for a little while. I did all this without success. I had bees everywhere, but not a trace of the queen. Dr. Miller says, and he is an authority, "When the queen must be found" (this was my condition exactly, and by this phrase I knew where I was at)—"put the bees through a sieve made up of a hive-body and a queen-excluder frame."

Great scheme! On paper it looked fine, and my boy and I both thought if we had been wise we would have tried the last scheme first. Just think of it! pass your bees through a sieve, and the remainder is a queen. No problem at all, for a problem is when you try to do a thing in an undoable way.

So we nailed a honey-board to the under side of a hive-body and shook into this sieve all bees from the frames and the hive, replaced frames in the hive, put the sieve on top, and awaited developments. Conditions were getting pretty tense as night was approaching, only two hours off, and we had thousands of bees in the air and in the sieve. Something was wrong somewhere. The bees would not go through the device. Then we smoked them, which started a few of them on the downward path. Smoking, I had often been told, had this effect; but I longed for a wholesale process, as this was too slow. At length I put the cover on the sieve and retired to have a smoke on my own account, believing it would be less irritating to the bees. Just before sunset I overhauled the contents of that sieve in a last effort, and decided that, first, the queen was lost; second, the queen was not lost. Either way it did not matter, for I had two queens, so I would divide the hive with the division-board, introduce a caged queen on each side, and let it go at that. The queenless side might accept; the other would take care of the intruder. This was done, and on examination a week later I found the old clipped queen in one side and a balled dead queen in the other.

Next day I opened the other two hives, found the queens without any trouble, put in the division-board, and the day following introduced queens to the queenless sides. One was accepted by the weakest hive, the other was not. A week later I tried again in the two hives where I had failed; but as the season was now far advanced I

felt I could not afford to open the hives again to overhaul the frames.

Does not Doolittle urge the importance of "millions in the hive" in the beginning of winter? So I proceeded to feed each side of the hives from above, night after night, until the bees seemed to be unable to take down any more. I noted particularly that No. 1, my original, and a very strong hive, took by far the most; No. 3, my second best, took down very little; but No. 2, the weakest, did fairly well. These facts are worth remembering in view of the developments in the following spring, and I had food for much thought in the summer and fall of 1907 in an endeavor to account for the unexpected way they behaved in the building-up season.

In the beginning of December, 1906, I bunched my hives side by side and enclosed them in a strong packing-box 8 feet long and 4 feet square, filling up every nook with dry leaves. I left an open space six inches wide in front of the entrances, and set a sloping portico to protect from strong winds and drifting snow. The entrances were contracted to 3 inches by $\frac{3}{8}$ for each division. The bees wintered finely, very few dead being found at the entrances or on the bottom-board at the end of winter. They had a flight the first week in January and again in the middle of February.

Toward the end of December I saw a dead larva at the entrance of the side of hive No. 3, in which was the new queen. I had seen a few eggs and the queen herself at the last examination, so felt hopeful. January 5 I saw four drones flying from this side, and now I had cause for wonder; but all I could do was to wait until spring.

During the winter my interest in bees continued to develop at a rapid rate. In my day I have had many hobbies, but this was the first with living animals I had ever got inrested in. Chickens had never appealed to me, though I had kept them in a perfunctory way for the sake of their product. Speaking of chickens reminds me of one of my neighbors who, for several years, kept the finest strains in the market, and most methodically followed all the rules and regulations recommended by the authorities. Never did I see such beautiful birds as his Wyandottes and Orpingtons: never were chickens so comfortably housed, methodically fed and cared for, yet not one egg did my neighbor get for eighteen months. Of course, we teased him unmercifully—that is part of the fun of suburbanites. When I was busy trying to introduce the duplicate queens, one of my boys was reading up the subject in the books. When he came to where it is told that in the spring a queen may lay as many as 4000 eggs in one day he dropped the book and exclaimed, "Why does not Mr. Thomson get a cross between one of our queens and his chickens? He would get eggs then for sure." Thomson's hybrids added a little to the gaiety of the village for a few days.

Two books I found specially interesting at this period, and some of my readers may be glad to hear of them. One was Mæterlinck's classic book on the bee, written in a style that is both poetic and scientific. It is not a book on practical bee-keeping, but is a charming study of the social arrangements of a hive. Even more fascinating to me is "A Level of Social Motion,"

by M. A. Lane, which is published by McMillan. Primarily this book is intended as a prophecy of the final outcome of the evolution of human society, the limit being when it shall become in stable equilibrium with its environment. Bees, the author considers, have already attained that condition; and, using the hive as a prototype, he works out a very interesting theory. Any bee-keeper who happens to be interested in sociological subjects will find in this volume an epitome of our present-day knowledge perfectly marshaled, and applied in a new way. A very important conclusion is arrived at.

Medford, Oregon.

EXTRACTING HONEY IN COLD WEATHER.

Leaving Honey on the Hives until Fall, and Extracting the Whole Crop at One Time by Warming it Artificially; the Use of Bee-escapes.

BY E. D. TOWNSEND.

Several bee-keepers in this part of the country have out-yards near the home yard, and draw all the honey home to extract. Mr. F. J. Miller, of London, Ont., Can., has a full equipment at his home yard, including a gasoline-engine, to run his extractor, honey-tank in basement, etc. The honey runs by gravity into the tank, and from the tank into the can on the scales. In this way there is no handling of honey, for it is necessary only to lift the full can from the scales and put an empty one in its place. Every thing is arranged with such complete system that Mr. Miller alone, with his one-horse wagon, draws home and extracts all the honey from 500 colonies.

One of the secrets of his success is in having plenty of empty combs, for he does not extract during the honey season, but on rainy days later, when nothing else can be done. He is thus independent so far as help is concerned, for if he gets in a "pinch" he can at least give his colonies more room.

We have drawn home considerable honey to extract, but we found the work a little on the strenuous order since we did not have every thing arranged for doing so much at once. With Mr. Miller's system I can see where failure might be turned into success.

Mr. E. E. Coveyou, of Petoskey, Michigan, has his two main bee-yards located along a railroad. He formerly shipped his eight-frame extractor, gasoline-engine, honey-cans, etc., to these yards each spring, and then, after the harvest was over, he shipped the apparatus and all the honey back to Petoskey where he bottled the honey for the grocery trade. Since his large bottling-room in Petoskey could just as well be used for an extracting-room also, he will now ship all of his honey there to be extracted, and he will, therefore, be able to have every thing arranged as conveniently as possible. In the spring the empty combs will be shipped back to the yards. Of course, there will be a large freight-bill to pay when following the new plan—possibly there will not be much difference in the expense of transportation between the new plan

and the old; and experience alone can tell which is the more economical.

It is evident that, if honey is taken from the hive with the bee-escape, and drawn home, it will be too cold to extract to good advantage, so it will have to be warmed artificially. The most feasible way to do this for the average bee-keeper is probably to set up a heating-stove in a small room in order to make matters more convenient, and also to save fuel. If this stove were set in the center of the room the supers of honey could be piled criss-cross around it. Since the hot air ascends, it is well to build an open platform two feet from the floor, on which to pile the honey, for supers placed next to the floor would not get warm, and they would have to be lifted up eventually to a warmer part. We have used three benches to good advantage, placed around the stove in the shape of a triangle, though leaving an open place through which to fire the stove. Of course, it would be possible to get the room so hot that the honey would be warmed, no matter where it might be placed; but in order to do this the heater should be large or else the room quite small. O. H. Townsend, of Otsego, Mich., has a plan similar to this, only he goes a step further and even cures that part of the honey that was not capped. Concerning this, he writes as follows:

For a fair flow of honey, the plan of extracting the honey after the flow is certainly a good one. If the building is put up properly the work can be handled very easily, and the honey extracted just as well in November as in July.

One thing must be remembered, however, that the supers, when they are stacked up, must not be covered tightly or else the moisture will not escape; and any unsealed honey will sour in two days in such a warm room. In taking off my honey last year I found that there were eighteen or twenty Heddon extracting-supers that had been put on very late, and these contained practically no sealed honey. I left them on the hives so that the bees might move the honey down if they would; but they did not, so I shook the bees from these supers on the ground in front of the hives and set them in my little bee-escape building, which is six feet square inside, with open screened windows. The weather was cool and rainy, so the honey was undoubtedly very thin, although I was not afraid of its souring, because of the cold temperature. I should have put it in my extracting-room; but as I was busy there I left it outside, where it was more out of the way. After these cases had been exposed to the damp air for five or six days it was set into my honey dry-kiln, where it was left just seven days, when it was extracted. I then found that it had been exposed to the warm air about four days too long, as it was possible to get only a part of the honey out of the combs. This thin watery honey was, therefore, evaporated down to the heaviest-bodied honey I ever saw, in seven days.

My building is built well. It is sheeted with planed unmatched boards, then covered with a good firm quality of building-paper, and finally sided over with ordinary beveled siding. The room at the end for warming the honey is 10 x 14 feet, and is lined on the sides and ceiling with the same kind of paper as that used between the sheeting and siding, this paper being lapped and fastened to the studding with lath, making good tight joints. I find that the paper retains the heat as well as or better than plastered walls, and it allows the moisture to pass through it, insuring a dry room. The paper cost 50 cents per roll of 500 square feet.

In the center of the room is a box stove with oval sides, the first joint of the stovepipe having a damper. As the fire-door fits tight, the draft can be regulated to perfection, which feature is important, as it allows the heat to be controlled, and prevents the waste of fuel. With wood of fair size the fire can be kept over night if the dampers are properly regulated.

When the extracting is to be done in cold weather I start the fire a day or two beforehand. As mentioned before, three or four days are necessary to ripen thin honey; and when the evaporation has been kept up long enough the covers can be placed tightly on the supers to prevent the further escape of moisture. There is some danger of melting the combs in the upper supers if the covers are tight; but if one is careful to keep the temperature right, there will be no trouble. I have quite an air-space above the supers of honey in the gable roof, which keeps the temperature of the room more nearly constant.

I do not depend upon the warm room for ripening all my honey, as it is left on the hives all through the season. However,

there is generally some that is not sealed, and this is greatly improved by the evaporation. O. H. TOWNSEND.

When following the plan of extracting the honey late in the year the combs may be freed from bees with the bee-escape or by brushing. At our Kalkaska yard, where both comb and extracted honey are produced in the same super, all supers are taken off with the escape. One day is sufficient to free the bees from a shallow super; but more time will be necessary to get the bees out of a full-depth super. Knowing that the Hutchinsons have had much experience in getting bees out of full-depth supers with the escape-boards, I asked Mr. Elmer Hutchinson, of Pioneer, Mich., to tell something of the plan. His letter is as follows:

We put only one full-depth super over an escape-board, for the bees are rather slow in leaving if more than one are put on at once. We give the bees a few vigorous puffs of smoke, driving down perhaps half of them, and then put on the escapes. If these are put on in the morning of a warm day, from one-half to three-fourths of the supers will be ready to come off by evening, and most of the others will be free of bees by the next morning. I have not noticed any difference in the time in takes, whether the combs are all sealed or only partly sealed; but a few dozen cells of brood will hold the bees in the supers a long time.

There is one thing about which I should like to caution beginners: Be sure the colonies have a queen; and, no matter how tight the covers are, keep a close watch, for there may be trouble from robbers. ELMER HUTCHINSON.

Remus, Mich.

USING HONEY FOR CANNING.

Honey Cheaper and Better than Sugar for Canning Fruit; Honey Better than Molasses.

BY MRS. FRANK MCGLADE.

In the March 1st issue of GLEANINGS, page 278, I notice that the strawberries put up with honey were all right, as I was sure they would be. So far I have used honey for canning fruit only in a small way, but have watched the results carefully, and am fully convinced that it can be used in place of sugar for any kind of fruit with much better results than if the sugar were used. When using honey I have never had a can spoil, and have always found the fruit far better and richer than that put up otherwise. We have been eating some peaches this winter that were put up three years ago, and in that time we have moved once. In every instance the "gude mon" has handed up his dish for a second helping, which is always a sign that it "hit the spot." I would, therefore, advise those wishing to try the honey to do so by all means.

Formerly, when I canned strawberries I took two quarts of good firm berries, just from the vines, stemmed them late in the day, rinsed them quickly in cold water, and drained in a colander until I could prepare another can. I put them in a stone crock and covered them with a cup of granulated sugar and set them in a cool place until morning. I then put them on the stove, boiled them well, and canned them. With this amount there is enough to fill a quart Mason jar, and a little over for a taste. When using the honey in place of sugar the same method is followed except that only half a cup of honey is used, which is poured over the berries so that it goes down through and all around them. We are careful to use good fruit, as one over-ripe berry may spoil the whole lot. Cherries, raspberries,

and blackberries may be canned, using about half the amount of honey that would ordinarily be used of sugar. The larger fruits, such as peaches, pears, quinces, etc., are also improved by the honey.

Fruit must be handled right in order to be good, and we must be free from other duties while canning it. A very safe rule is to follow whatever plan has been found successful, substituting half the amount of honey for the sugar. I am sure no one will be disappointed.

For cooking purposes, making pickles, etc., honey is just fine. We never buy molasses, corn-syrup, or glucose—"ugh!" You should see some of my ginger-bread which Mr. McGlade says is the "cake that takes." Here is the recipe. Try it for yourself.

Two eggs, cup granulated sugar, cup and a half of honey, cup of sour milk or buttermilk; cup of butter or lard; teaspoonful of cinnamon and a teaspoonful of ginger. Beat all together and add two teaspoonfuls of soda dissolved in a little hot water; flour to make a thin batter (about five cups). Bake slowly.

We use honey in making pumpkin pies—a generous teaspoonful to the pie. Furthermore, we use honey on the table every day, and our little boy never tires of it. He helps himself with a spoon whenever he likes, at mealtime or between meals, and has not had a cold nor seen a sick day this winter, although he runs and plays out in the fresh air in all kinds of weather. Of course, honey can not be given entire credit for this, but it helps, and is cheaper than doctors' bills.

Some have asked whether fruit can be put up cold by simply filling the can with the fruit, covering it with honey, and sealing. I have never tried it, because I don't believe the fruit would keep or be good; but if any one wishes to be convinced, let him try it, for it would cost only about seventy-five cents.

Hebron, Ohio.

FULL SHEETS OF FOUNDATION IN SPLIT SECTIONS A SUCCESS.

BY JAMES P. HOWARD.

In reply to the footnote at the end of Mr. Atwater's article on the use of full sheets of foundation in sections, p. 152, Feb. 1, I can say that we have used them to some extent for the past two years. We used the Coppin split section, which is made in two separate pieces. To fill in the foundation, a *holder* is placed in a *form*, and a row of the *half-sections* laid in, when the holder is keyed up in the form so that the sections are held in exact shape to go into the super; then the sheet of foundation, cut to the exact size to fit the row of sections, is laid on, the other half of the sections laid on, then a piece of board of suitable dimensions placed on the sections, and pressed down *very* firmly. I pound it with some solid light weight, after which I grasp the holder so that the sections can be held in place, lifted from the form, and placed in the super.

In the first season's trial I don't remember any failure of sections being *completely* filled and finished in *fancy* shape—not a single pop-hole anywhere.

We tried still more of them the last season, with about the same results during the first half of the season; but in most of the supers filled

later there were more or less brace-comb attachments to the fence separators, which were a serious objection wherever they occurred. It seemed to be caused by the sagging and *bulging* of the foundation, bringing it too near the separators. The foundation used was all of the same lot, and all other things and conditions the same so far as we could see, except the weather, which was very cool the past season. On the whole we consider it a success. The sections are $4\frac{1}{4} \times 5 \times 1\frac{3}{8}$, and fit finely in the regular Ideal supers.

LIQUEFYING CANDIED HONEY.

In the light of our experience "in this locality," Mr. Holtermann's statements in the last two sections of his article, page 145, seem very absurd. Honey in the brood-chambers of our hives, when candied, remains so until thrown out, and some is always thrown out of some hives as soon as the bees began to uncup any in the fall. I think he would get very tired of waiting for such honey to liquefy at a temperature of 100 degrees.

Milwaukee, Wis.

EXPERIENCE WITH FULL SHEETS OF FOUNDATION FASTENED ON ALL FOUR SIDES OF THE SECTION.

Mr. Root:—In the issue for Feb. 1 you ask for reports from those who have used sections with foundation fastened on three or four sides. We used several thousand the past season with fastenings on four sides in 4×5 sections in Danzenbaker supers, and the product was entirely satisfactory. I believe there were not two cases of ill-shaped or unmarketable sections in the whole of them.

The hives were fairly well shaded, and possibly that might help a little in preventing sagging and buckling. But in the same yard we used sections with foundation fastened only at the top in the usual way, and the honey was just as good in every way except some that was gathered later, and also some where only narrow starters were used.

I would say that, so far as quality of finish is concerned, nothing could be finer than the honey produced on foundation with four sides fastened; but the extra work is just that much added to the cost of production; and, in our experience last year, it was entirely useless.

CONTINUOUS SMOKE THROUGH COMBS ON A WHEELBARROW TO STOP ROBBING.

Last fall I discovered what I think is a very good plan for getting the upper hand of the robbers when taking off honey to be extracted. We were only about half through a yard with extracting, and the robbers were getting so bad that it was next to impossible to do any thing. Robbers are bad in proportion to the size of the yard, and this was a good-sized one.

I took a tin dish and fixed it under the wheelbarrow in such a way that, with a small fire in it, it would send smoke up through the set of combs in the super on the wheelbarrow, and scarcely a bee would venture in. At first I thought it might injure the honey flavor; but if the right amount of smoke is used, and not too long continued, it will be entirely impossible to detect a trace of smoke in the honey.

Parma, Idaho.

H. E. CROWTHER.

EXTRACTED-HONEY PRODUCTION.

Straining the Honey.

BY W. Z. HUTCHINSON.

Continued from last issue.

An extractor with a strainer in the bottom probably possesses some advantages. One is, that it can be set at a less height from the floor, as no space has to be used for the strainer-tub. We have always used an ordinary galvanized wash-tub, with a honey-gate in one side near the bottom, and the top covered with cheese-cloth sewed to a wire hoop slightly larger than the top of the tub. We have several of these cheese-cloth strainers; and when one becomes so filled up or covered with pieces of wax that it strains slowly we remove it and lay it over another tub, or a barrel of cappings, until the honey has all drained through, when the accumulation of cappings and thick honey is scraped off with the honey-knife. I have been told that it would be better to have the cloth strainer more in the nature of a sack, nearly large enough to fill the tub and rest upon its bottom; then the sides of the sack would remain free from cappings; and act as a strainer without becoming clogged. In a horizontal strainer, such as we have been using, the trouble is that the cappings settle upon the strainer and soon clog it, while the sides of a sack, being perpendicular, remain free from cappings, and do not clog in a long time.

FILLING THE CANS.

Honey produced according to the plans described in the previous articles is ready to go directly from the extractor into the cans or barrels; in fact, it is better that it should be canned up at once, as there is less loss of flavor or aroma. There is also a saving of time, as it is only necessary to remove a full can and put under an empty one while doing the work of extracting. To know when a can was full, without standing by watching it, was one of the problems that I had to solve, and I did it by using an electric alarm, on the principle of an electric door-bell; in fact, I used the identical outfit that is used for a door-bell. Almost every one is familiar with this arrangement that rings a bell when a current of electricity is sent through its mechanism. When the button in the door is pressed, an electric circuit is completed, and, as a result, the bell rings out in the kitchen, or wherever it is placed. If the complete filling of a can or barrel could be made to complete an electric circuit within which is

an electric bell, then an alarm would be given. I solved the problem by so arranging matters that the raising of the brass beam of a pair of platform scales closed the circuit. The battery used is one of the ordinary dry-cell batteries, such as are used for telephones, door-bells, or for furnishing a spark for a gasoline-engine. Be sure to get a good battery. If you can get only the cheapest kind, better get two cells and connect them, as the connections upon the scale-beam are

PERFECTION DUPLICATING SCALES.

This arrangement not only weighs the honey but it closes the gate when the can is full, and rings a bell to let the attendant know that it is full. It can be used to weigh almost any size of package or commodity, duplicating the weight exactly, and doing the work automatically.

not as close as are usually made upon a door-bell, and it requires a good strong current to overcome these imperfect connections and ring the bell. It won't answer to depend upon a bell that does not *always* ring—better not have any bell at all. Connect the battery and the bell by means of the insulated wire that comes with the bell, then cut one of the wires in two, scrape off the covering for a distance of two or three inches from each end, wind one end around the brass beam of the scales, near the back end, then support the other end just slightly above the other end of the beam, when the latter is depressed. Put your can on the scales, set them to the desired weight, turn on the honey and go about your business, provided the business is not out of sound of the bell. As soon as the requisite amount of honey has run in, the beam will rise and touch the end of the wire above it, thus completing the circuit and ringing the bell. The scales may be set a pound or two short, and then set at the correct weight after the alarm has been given, and the filling completed.*

AUTOMATIC SCALES THAT CLOSE THE GATE WHEN THE CAN IS FULL.

There is just one objection to the electric alarm just described, and that is, something may hap-

CHEESE-CLOTH STRAINER ON TOP OF A TUB.

This tub is set under the honey-gate of the honey-extractor, and the cans are filled from the honey-gate in the side of the tub. Extracting, straining, and canning are all in operation at the same time

pen unexpectedly, making the electrical connections imperfect. A bit of wax once got upon the beam of the scales, just under the spot where it ought to have touched the wire above when it raised, and great were the consequences. Thanks to the inventive genius of Mr. E. E. Coveyou, of Petoskey, Michigan, even this point has been overcome. He has perfected and used successfully what he calls his Perfection duplicating scales, which not only give an alarm when the can is filled, but actually close the gate in a positive, certain manner. Let me describe it:

First, there are two platforms suspended at the ends of a beam hung upon a pivot at the middle. This part of the machine is an almost exact duplicate of the druggist's balancing scales. Upon one of the platforms is placed a 60-pound can full of honey, or its equivalent in weight. Upon the other platform is placed the can to be filled. When the can becomes full it balances the can upon the other end, and thus it settles down. As it goes down it draws down a small brass rod connected with that end of the balance. The upper part of the rod is not straight, but bends out from the standard of wood to which the various parts are fastened. Just in front of the bent part of the rod is one end of an "elbow" of iron or steel; and, as the rod is drawn

THE ELECTRIC DOOR-BELL ALARM TO INDICATE WHEN THE CAN IS NEARLY FULL.

The plan of wiring up the battery, bell, and scales is here clearly shown. The contact at D is made when the beam lifts, connecting the electric current.

*This plan is also clearly shown by the engraving accompanying Mr. Townsend's article, p. 761, June 15.

down, the bent portion presses against the end of the elbow that is in front of it, and swings it around slightly, thus throwing the other end of the elbow to the right, forcing it out of a notch cut in the side of an upright rod, the lower end of which is fastened to the upper part of the honey-gate. When this last-mentioned rod is thus released it quickly shoots downward, closing the gate. The force that causes it to shoot downward is a spiral spring, coiled around the rod between a "bulge" near its lower end, and a projection from the standard that comes out just below the "elbow" above mentioned.

As the rod goes down, a projection on its upper end catches the projecting lever of a little gong, causing it to give out a sharp ring. When the gate is again opened, the rod rises, the spiral spring is compressed, the end of the "elbow" catches in the notch in the side of the rod, thus holding it up, a little spring behind the left end of the elbow pulling the latter around and causing it to catch in the notch.

The honey from the extractor or from the tank, as the case may be, is brought to the gate through a rubber hose. When the gate is opened, the honey continues to run, of course, until the can is full, when it again descends, which pulls down the rod, thus forcing around the elbow, again releasing the rod having the spring, when down it shoots, cutting off the stream and ringing the gong.

As a double precaution, there is an electric bell that rings when the can is full and descends, thus making the connection. This bell rings continuously until the full can is removed.

DISPOSING OF THE CROP.

In my experience, such honey as this, thoroughly ripened, thick, rich, and aromatic, can be sold at from one to two cents more per pound than the ordinary honey thrown upon the market; but in order to do this the right class of customers must be found. Such customers will be found among those who buy honey for their own use, or to put it up for a retail trade. It will require some effort and some expense, however, to find these customers. You must advertise, and send out samples. Of course, this costs something; and if a man were to remain in the business only one year or for a short time it might not prove profitable—probably would not; but a man can gradually build up a trade and secure a class of customers who will eventually buy his honey without any advertising. After I had advertised only one year, and sent out samples and filled orders, I began receiving orders the next year from my customers of the previous year. They did not even ask for samples; they said, "If your honey is like that of last year, you may send me so many cases," and they sent on the cash.

Now, friends, isn't it worth while to have such a trade—to be able to sell your honey, year after year, to the same men, those who willing to pay you from one to two cents above the

market price, and send cash with the order, because they *know* that no finer honey can be produced, and that it is worth what you ask for it?

The whole thing can be told in a few words: Produce honey of a superior quality, and then let consumers know about it—the latter is fully as important as the first.

Flint, Mich., March 13.

To be continued.

ANOTHER INSTANCE OF DISHONESTLY GRADED HONEY.

BY S. J. GRIGGS.

We inclose you a photograph of a case of honey which we received in the car of honey which we bought from the — Co., of —. We found in looking this honey over that we had about 200 cases of this class of goods. The four bottom sections were placed along the glass in order to hide the rest of the honey and to deceive the purchaser. We have written these people several times, and on the 200 cases we secured a refund of \$150. A case of this honey originally cost \$3.50, so this leaves us a cost of \$2.00 per case, which you know we could not get for it. We found a card in several of these cases of the — producers, —; and we are satisfied that a large percentage of it came from them. Mr. N. E. France has written them several times, and we are having some correspondence back and forth, but the eastern dealers must do all in their power to stop this practice, as it is certainly an outrage for people to have such stuff as this poked on their hands.

We think you can do considerable good by

A SAMPLE OF DISHONESTLY GRADED HONEY.

The four full sections at the bottom were placed next to the glass to deceive the purchaser.

putting this in GLEANINGS; and while you can do as you like about mentioning any names, they ought to be shown that this matter has got to be advertised if they continue this kind of work.

Toledo, O., April 30.

[We have suppressed the names for this time, but desire to warn the parties that if this kind of work is repeated again we shall give the names the prominence they deserve. The question may arise, "How will the parties know they are the ones referred to?" The "shoe will fit" when it is tried on. If it doesn't, it won't need to be worn.—ED.]

A NON-SWARMING RACE.

What Can be Expected of Such a Bee? Some Statistics to Show the Percentage of Swarms in Several Apiaries in Switzerland.

BY DR. BRUNNICH.

On p. 1554 of GLEANINGS for 1907 Dr. C. C. Miller, in speaking of our race of Swiss bees, says, "If not more than two or three in a hundred colonies are likely to swarm, I'd like a queen of that stock, no matter how black."

This note induces me to tell something about swarming in our country, where the conditions for the crop are, I think, not greatly different from yours. Our principal crop lasts till the hay harvest—middle of June; after that, but little honey comes in except in localities where there are great forests. In earlier times, when bees were kept in straw hives, and when sugar was too dear for feeding, the colonies swarmed but very seldom; and when they did swarm it was not later than the middle of May. This is accounted for by the process of selection and acclimatization, because bees that swarmed much and late would die and not propagate. So it was that our grandfathers had a stock which began to breed very late (end of March); but they would then breed with great intensity to be ready when the honey harvest began. After the harvest, the brood began to diminish; and in August there was but very little brood in the hives. This bee, so well acclimatized, possessed a great longevity, and, in consequence, the hives were always full of bees, though there was but a small amount of brood.

Then the movable frame came to our land, and, soon after, a great many of our bee-men were seized by a certain disease—the mania for strange races of bees. They imported Cyprians, Italians, and especially the gentle and productive Carniolans. This disastrous blending of our stock with strange blood generated, in most bee-yards, a deterioration of the bee, and bee-keeping in straw hives gave such poor results that they began to diminish rapidly. The Carniolans brought us a mania for breeding and swarming, and the Italians destroyed the harmony of the brood-nest by the changed conditions. Those Italian hybrids began to breed very early in the year, and hence had great losses in spring; further, they were short-lived in our climate, so that they were poor in numbers though rich in brood. Many a bee-keeper "crossed" himself

about the quickness of the stiletto and the kleptomania of the Italian bees. By the way, I can not sufficiently emphasize the fact that our black race, as well as the Italian and Carniolan, is very gentle if purely bred; but nearly all hybrids are very cross.

When Mr. Kramer, and others later on, recognized the superiority of our native stock it was, fortunately, not too late. There still existed many remote bee-yards where were found the old home-bred bees with their noble qualities. They were supported by the great *hardiness* of the race, which tended, in spite of all intermingling of foreign races, to hold its own against the other races. By the aid of rational breeding, thanks to our mating-stations, we now have in many bee-yards a good number of queens—enough to satisfy all reasonable demands. I have some queens in my bee-yard which cause the heart of the bee-man to leap at any time of the year, particularly at harvest time—queens whose genealogy is noted in my books for several generations back, including that of the drones also. Their bees are exceedingly long-lived, as

FIG. 1.—DR. BRUNNICH, OF OTTENBACH, SWITZERLAND, IN THE ACT OF HIVING A SWARM.

FIG. 2.—A SWARM IN A VERY INACCESSIBLE PLACE.

Notice at the right a small cluster of bees around the caged queen.

are the queens. They begin breeding late, but then breed with vigor, so that in a few weeks the hive is full of bees. The brood-nest in spring is wonderfully regular. It is one of those queens that lived eleven months with her daughter in the hive. We do not clip our queens; but about five years ago I began to put on every queen a distinguishing mark every year, varying with different colonies.

How about the percentage of swarming of our stock? Dr. Miller demands not more than 3 per cent from all colonies. What does that mean? Let us suppose 100 colonies which are never requeened, but which supersede themselves at the proper time throughout many years. Then they ought, in 100 years, to swarm 300 times (3 per cent supposed). One colony, therefore, in 100 years swarms 3 times—that is, once in $33\frac{1}{3}$ years. Well, doctor, you demand a stock which supersedes ten to twelve times without swarming. Then it is allowed to swarm, but afterward will have to support itself for 33 years, and so on. I think, doctor, this is asking a little too much, is it not? I must confess that our old stock, when

still dwelling in little straw hives, swarmed often-er than every 33d year, and it was, indeed, compelled to do so. With the uncertainty of the honey harvest, and without feeding, these colonies would have diminished rapidly.

How is it to-day with the swarming of our best stock and with the movable frames? It is sure that our large hives are fit to restrain swarming; but, unfortunately, there is no bee-yard that has pure stock for a number of years. The purifying of a race takes many years; although the conditions with the bee are most favorable at mating-stations, yet scientific experimental breeding is not practiced much longer than about ten years. I myself have reared queens for only seven years, and therefore I can not give a decisive judgment. But I can, however, give you some statistics. Mr. Spuhler gives me the results of the past seven years in the field of the association of bee-keepers of Zurich and surroundings. Of these, in the year—

1900,	2733 colonies cast	569 swarms,	or 20.8%
1901,	3110 colonies cast	162 swarms,	or 5.2%
1902,	3158 colonies cast	145 swarms,	or 4.6%
1903,	3116 colonies cast	351 swarms,	or 11.0%
1904,	3441 colonies cast	321 swarms,	or 9.4%
1905,	3706 colonies cast	488 swarms,	or 13.2%
1906,	4020 colonies cast	590 swarms,	or 14.7%

This gives an average of 11.3 per cent of swarms. But you must remember that it was not 11.3 per cent of the colonies that swarmed; for, taking care of the after-swarms, it might, perhaps, be 6 or 7 per cent of swarming colonies. Further, it must not be forgotten that, in the case of about 3000 or 4000 colonies, there were still a great many hybrids; and last, but not least, not all the bee-keepers were experienced enough—perhaps not even willing—to suppress

FIG. 3.—THE BEES OF THE SWARM SHOWN IN FIG. 2 IN THE NEW POSITION OVER THE QUEEN-CAGE.

FIG. 4.—DR. ERUNNICK'S SON ABOUT TO PLACE THE CLUSTER IN A HIVE.

swarming as much as possible. It is a well-known fact that a skillful apiarist will reduce swarming by not giving much drone comb, by enlarging at the proper time, etc. I think, therefore, that Dr. Miller will not be totally dissatisfied with these figures.

Mr. Spuhler, an old, experienced, and able apiarist, tells me that his average of swarms in those last years (he has 100 colonies at home and in two or three outyards) is about 6 per cent, or of swarming colonies about 4 per cent.

I can give you still better results from another friend of mine, Mr. Serf, also an experienced queen-breeder. He gives me the following figures, having in one single yard about 60 colonies (in our country you can not have profitably more than 60 colonies in one place).

1898, 12% of swarms.	1903, 0% of swarms.
1899, 0% of swarms.	1904, 2% of swarms.
1900, 24% of swarms.	1905, 5½% of swarms.
1901, 0% of swarms.	1906, 1½% of swarms.
1902, 4% of swarms.	1907, 5% of swarms.

This gives for the last ten years 3.3 swarms from 100 colonies. What do you say to this, my good Dr. Miller? Mr. Serf has, like myself and many others, a short honey harvest; but he has a good one because he has a very fine stock of bees.

That you do not possess in America a satis-

factory race of bees is no enigma to me. It is due to the mania for new races and the roaring "tam-tam" of recommendation of foreign races that it is impossible for your bees to assume a fixed type and to become acclimatized.

And now a few words to Dr. Miller concerning page 36. You wonder how I can have the arrogance to say "that I am not yet convinced that a pure strain of blacks would not be the best for you under *your* conditions." I will tell you. In GLEANINGS for 1905, page 370, you can read a most interesting notice from Mr. L. H. Scholl, of Texas, whom I consider from this note alone to be a very clever and scientific queen-breeder. He told you that he possessed an exceedingly fine strain of blacks—fertile queens, excellent honey-gatherers, and—think! *gentle* bees. Queen-rearing was then an easy thing, thanks to the stability of his race. But it was otherwise when he introduced the beautiful yellow bee. In brief, the introduction of the Italian bee signified for him the deterioration of his

bee-yard. Well, doctor, should not that which is possible in Texas be possible also in a northern climate?

A word about Berlepsch, who seems to be totally unknown to our American colleagues. In the "History of Bee-keeping," by Bessler (1885) the author says: "Through his book, 'The Bee,' the best existing apistic work till now, he has acquired immortal fame; and as long as bees continue, the name of Berlepsch will shine with the greatest splendor." Berlepsch invented the frame in 1852, some years after Dzierzon had given us the movable comb, which was fixed only at the bottom in a rabbet. Undoubtedly, in regard to the movable frame he was to Europe what Langstroth was to America. It is true it was Dzierzon who gave us the theory of parthenogenesis; but it was Berlepsch who, by the aid of Leuckart and Siebold, *proved* this theory to be true and gained the general acknowledgment of the scientific world to it. It was, indeed, with unflagging zeal that he investigated and solved the finest problems in apiculture; and what he claimed, he proved by numerous experiments backed by an exceedingly keen intelligence. It is a great pity that his work, "The Bee," is quite unknown in America, for even to-day it is a great delight to read this old book with its im-

mense number of interesting details concerning bees.

I do not quite understand W. K. M.'s remark, "France is not one whit behind Germany in scientific research, and yet it does not accept German ideas any more than we do," etc. Please look at Cowan's "Honey-bee," chapters on parthenogenesis, digestive apparatus, structure of the glands, etc., and you will find that, notwithstanding your assumption, a great many German researches have been accepted by all nations. But these are useless quarrels. We had better take the good, wherever we may find it, be it in Russia or America.

Ottenbach, Switzerland.

THE DEVELOPMENT OF LOCAL BEE-KEEPERS' ASSOCIATIONS.

BY R. F. HOLTERMANN.

There is developing in Ontario a strong activity in the county or local bee-keepers' association, and the movement is receiving every encouragement from the Department of Agriculture. Our province (in standing equal to one of the States of the Union) gives to the various agricultural bodies such as bee-keepers, fruit-growers, vegetable-growers, dairymen, short-horn, Ayershire, horse-breeders' associations, an annual grant. This grant is in proportion to the importance of the industry and to the use the association makes of the money contributed. I must confess, when I see the results we obtain from this help, that it is a matter of surprise to me that the States of the Union do not adopt the same policy. The outlay, after all, is not great, and yet it is the very thing needed to give foundation for co-operative action to those interested in the development of the various branches of agriculture. I feel sure that all that is required to secure this system or policy in the United States is a brief, active, and energetic campaign on the part of those interested. If such demand such aid, it will be given by the state.

That the desire for such help is strong, I know from coming in contact with people on the other side of the line. The feeling, however, appears to be that *this is not the general policy of the state*, and therefore there is no use in looking for a grant. Let the agricultural body at large ask for it; let the agricultural press take it up; let

E. T. FAINARD, SECRETARY E. J. MILLER, PRESIDENT OF
AND TREASURER OF THE—
THE—
MIDDLESEX CO. BEE-KEEPERS' ASSOCIATION.

them point out that agriculture does not receive the assistance that its importance demands, and the help will come. Our Ontario Bee-keepers' Association receives a grant of \$500 per annum. It gives \$200 per annum, to be divided between the various local or county associations in affiliation with itself. So far this has given the affiliated society from fifteen to twenty dollars of a grant.

The payment of one dollar gives a bee-keeper membership in the affiliated society, also in the Ontario, and has given each member the premium a member of the Ontario receives, which has in the past been a journal, a smoker, or a queen.

The local society can not become affiliated with the Ontario until it has at least ten members who also, as per the above, become members of the parent society, and the grant given it must be spent in certain specified ways in keeping with the advancement of bee culture.

The Department of Agriculture, I believe, is prepared to help bee-keeping more than it has, and I think it is prepared to give the Ontario association a larger grant if it can use the money to advantage, and if the affiliated societies become more numerous and active, the Ontario should give a larger grant to encourage this activity, and the latter will then be able to submit the best possible plea for more money.

In addition, the Superintendent of Farmers' Institutes, Mr. G. A. Putnam, is providing lecturers to affiliated societies.

OFFICERS OF THE SIMCOE CO. BEE-KEEPERS' ASSOCIATION.
JOS. M'GINNIS. DENNIS NOLAN. C. H. WILSON.

ties. This has been done in New York, Pennsylvania, Wisconsin, and other States for years, and this movement will, no doubt, increase the usefulness and number of the local societies.

Those of us who have been in close touch with association work realize that State and provincial associations, in affiliation with the National, are desirable and necessary in order to give greater strength and influence to the National. It is also desirable and necessary in order to reach the largest number of bee-keepers. In order to carry out the greatest educational campaign, and reach, as it were, the very door of the bee-keeper, we must have county or local associations in affiliation with the State or provincial organizations, and these, again, with the larger. We realize that there is something needed to make bee-keeping a more permanent business with half of the bee-keeping population. Let us treat the industry more seriously and it will reward us.

RECENT LOCAL CONVENTIONS AND SOME OF THEIR OFFICERS.

On April 18 the Simcoe County Bee-keepers' Association met at Barrie. The attendance was good. Reports handed in indicated that bees had wintered well—probably not more than 10 per cent having perished, and these died on account of having improper stores for winter. Three members had their bees still in winter quarters. As is generally the case in Ontario, an unusual quantity of stores had been consumed by the bees

during the past winter. R. F. Holtermann was present, and in speaking on the subject assigned him, "How to increase the average yield per colony," gave some of the following points: Give more and better stores, contracting the combs to the strength of the stock, for winter. When possible, shelter the apiary from prevailing winds. Use larger hives; shade and ventilate hives and prevent natural swarms, and thus have more uniform colonies; pay more attention to blood in bees.

Pres. C. H. Wilson acted as chairman, and Dennis Nolan, who is also a director of the Ontario Bee-keepers' Association, made an excellent secretary.

MIDDLESEX BEE-KEEPERS.

The above association met at London with Pres. Miller in the chair, who is also president of the Ontario Bee-keepers' Association. In relating experience, Mr. Kimball described a bee-house for wintering bees above ground. It had a four-inch hollow wall in the center, with 12 inches of sawdust inside and 8 inches of sawdust packing outside, giving four walls of lumber. In reply to a question, he admitted that sometimes the temperature varied greatly in a short time, but he did not find that this injured the bees. An inlet and outlet for fresh and foul air was provided.

John McEwen related his experience in wintering bees packed in outside cases or summer stands, and showed pretty conclusively the desirability of hav-

NO. 2.—A. I. ROOT'S "CABIN IN THE WOODS" ON OUR ISLAND NEAR OSPREY, MANATEE CO., FLA. SEE ARTICLE ON ANOTHER PAGE.

NO. 3.—A. I. ROOT'S "COTTAGE IN THE WOODS" NEAR BRADENTOWN, FLA.

ing the bees sheltered from cold winds during the winter. In the spring, as soon as weather permitted, he filled the combs next to the sides of the hive with syrup (two of sugar to one of water). This resulted in the development of much early brood.

E. Bainard, the secretary, advocated stimulative feeding in late summer, where there is no honey-gathering by the bees after basswood. He had found that old queens would not lay, and young queens would lay; but in the latter case the bees would not rear brood from the eggs deposited.

SALT AND WATER.

Robt. Wallace, Jas. Armstrong, F. A. Gemmell, and John McEwen all strongly advocated giving bees regularly salt and water, a tablespoonful of salt to an imperial gallon of water.* Mr. McEwen stated that the day previous to the convention his bees had taken up 8 gallons of this water by means of feeders set out in the apiary by him.

D. Anguish and F. A. Gemmell strongly advocated flax chaff for packing for bees wintered in outer cases.

Quite a discussion took place in connection with foul brood, and the following resolution was passed unanimously: "That the Middlesex Beekeepers' Association would earnestly point out the need of a larger government grant and more inspectors to stamp out the disease known as foul brood."

R. F. Holtermann, in recognition of services rendered, was elected an honorary member of the association.

In connection with the above resolution the following announcement has appeared in the *Farmer's Advocate*: "At least as many foul-brood inspectors will be engaged this season at last, and probably one or two additional."

Brantford, Ont.

BEES STORING HONEY BELOW THE BROOD.

Do they Ever Do it if there is any Room Above?

BY J. E. HAND.

I am pleased to note that Dr. Miller, p. 1488, 1907, does not wish to go on record as saying that bees in Illinois are as likely to store their honey below the brood as above it. He even goes so far as to say that their general preference is to store it above the brood. However, I prefer to call it instinct. Now, if we admit that the general preference, habit, or instinct of bees is to store their honey above the brood, then we must look for some cause other than general preference, habit, or instinct that would lead or compel them to do right the reverse. I can think of but one

thing that would cause bees to go counter to their natural instincts; and that is, an abnormal condition of the colony, which may be brought about in various ways. However, I am inclined to the belief that in Dr. Miller's case the cause was a played-out queen.

I would consider the act of storing and capping honey below the brood with plenty of room above it as *prima-facie* evidence of an abnormal condition of the colony, and for this reason a colony that would so store and cap honey would not be in condition to remove it quickly, since a vigorous queen is the all-important factor in this operation. I hardly think the doctor will care to say that those colonies were in a perfectly normal condition after what he has been saying of late about his superior strain of comb-honey makers, for it is needless to say that such colonies would be of no account for comb-honey production. However, if he will say that such was their condition, then I will cheerfully modify my statement to which our good friend takes exception.

Birmingham, Ohio.

THE NEST OF THE BALD-FACED HORNETS.

BY E. F. ATWATER.

The nest shown was about 18 inches long, and still being enlarged along the line where a careful search will show one of the inmates at work on the left-hand side. The insects are here call-

NEST BUILT BY BALD-FACED HORNETS.

The nest was 18 inches long and still unfinished.

ed "bald-faced hornets," and the adjective *big* is also always applied. They are almost as large as small bumble-bees, and not fierce unless disturbed. Near by was another and smaller nest of later establishment.

Meridian, Idaho.

* Let our United States friends remember that their standard measure is what we call *wine* measure; ours is *imperial*, which, of distilled water, weighs 10 lbs. I have been somewhat amused by a well-known United States bee-keeper's reference to the mistakes of Canadians as to the number of pounds of honey in a gallon. He stated that a Canadian scientist had given this as 10 lbs. I venture to say the scientist said *distilled water*, not honey. Again, the actual weight of well-ripened best-bodied honey, imperial gallon, our measure, will be found to be what Canadians state.

ARE BEES REFLEX MACHINES?

**Experimental Contribution to the Natural History of the Honey-bee by
H. v. Buttel-Reepen, Ph. D. Translated by Mary H. Geisler.**

Continued from April 1st issue.

MEMORY OF PLACE IN BEES.

In general, we should not set up a new unknown force to explain natural phenomena until it has been proven that they can not be explained by the known forces.—*Aug. Weismann, Keimplasma*, p. 539.

According to Bethe, bees are "led back to the hive by a force entirely unknown to us. This force does not adhere to the hive itself, and it does not lead bees back to the hive itself, but to the place in space which the hive usually occupies. It does not act at boundless distances. It is an old experience of bee-keepers that they can take a colony to another stand without fearing that the bees will return to the old place, if the new spot is only more than six kilometers from the old. It follows, then, that this force acts at most at a distance of six kilometers, since the impulse to return to the hive is the strongest of all impulses in bees. But I believe that the zone of action of the force is not a circle with a radius of six kilometers, but of only between three and four kilometers. If the circle had had a radius of six kilometers, then the bees of the transposed hive would be back into the circle of action if they got more than half that distance near the old position in foraging, and would have to return to the old place. But this only happens if the old position is less than six kilometers away from the new. We must, therefore, accept something near three kilometers as the boundary for this circle of action for this force." (Bethe, l. c., p. 89.)⁵⁷

I believe that in the foregoing, and likewise in many other of his observations, Bethe furnishes such excellent proof of the existence of memory for location that one can hardly wish anything better. But Bethe supposes "a force unknown to us," with which we do not know what to do, which offers support for every investigation. Under this head I must depend more strictly upon Bethe's work in order at the same time to point out the errors in the chapter, "How do Bees Find the Hive?" (Bethe, l. c., p. 72.)

THE "PATHS" OF BEES AND THEIR DIRECTION.

If bee-hives are placed on an open heath, with no elevations such as trees or bushes, the particular kind of flight toward and away from the hive may be studied, undisturbed by local conditions. In August, 1898, I had opportunity to prove this condition on a moor in the neighborhood of Oldenburg, corroborating entirely my earlier experiences.

The colonies were established on the moor by the bee-keeper shortly before the buckwheat-flow. The hive-entrances faced the east. On the first day the flight was weak, for as yet there was nothing to gather. The bees flew out irregularly in smaller or larger circles in all directions. There was nothing to be seen yet of "a path."⁵⁸ Great buckwheat-

⁵⁷ The "unknown force" must act at much greater distances under certain conditions, for other observations show that bees have flown five, six, or even over seven kilometers further under extraordinary circumstances. (See *Bienenzeitung*, X., No. 14; ditto III., No. 9, Dzierzon; Le Rucher, Amiens, 1876, IV., p. 30). In these cases there was no forage near at hand. According to Dzierzon, some bees under these circumstances scented a large "hundred-acre" rape-seed field which lay far outside their usual circle of flight. Roth, the leader of the Baden school for bee-keepers, in Durlach, observed that some of his bees returned in thirty minutes with full loads from a buckwheat-field six kilometers away. Granting that Roth's bees flew to the buckwheat-field from the south, there is no reason for thinking that bees from an apiary at the same distance toward the north had not hastened to this same nectar supply. Now if, for experiment, a colony should be taken from the southern apiary to the northern one, then they fly south to the buckwheat-field, and there, coming into the field of action, would again return to the southern apiary. The "unknown force" would reach twelve kilometers in this very possible case. If it be asked from what distance bees can find their way back, the answer can not be made in kilometer measurements, for it depends upon whether the bees in their flight of orientation (see the same) or in their search for food have flown to greater or less distances, upon the definite direction of the forage and the general orientation.

⁵⁸ "It is well known that, in front of the entrance to a strong colony, there is always a long dark cloud formed by the bees constantly going back and forth." (Bethe, p. 75.) This is Bethe's "bee-path."

fields stretched toward the north as well as to the south. When the flowers opened, the mode of flight changed. Part of the bees flew from a point close to the entrance, sharply to the left (north) and another part sharply to the right (south). In consequence of this the paths were very short, the terminations (the hives stood close to each other) coming together in a common wave.⁵⁹ It is apparent from this that the position of the pasture determines the direction of the flight in and out.

When, later, the buckwheat-fields ceased blooming and the moor was in full bloom, the same short, though perhaps a little lengthened, paths were seen; but the common wave was higher and apparently somewhat larger, from the great numbers hastening in from all sides.

"Long paths" of bees, which Bethe describes as normal, are found chiefly only in the case of bees in gardens where trees, houses, etc., modify the flight. The view is wrong (Bethe p. 80), that "it is a well-known fact to bee-masters that the steepness of bee-paths varies with the weather."⁶⁰ It is an error further, that "bee-paths always go out from the hive in the same direction with slight fluctuation. This is almost always east, southeast, or south. Not only for this reason, but also because bees need sun to be industrious, the bee-keepers place their hives toward the south or east." (Bethe, p. 81.) This last assertion is erroneous.⁶¹

It is clear from the above, even if Bethe had not stated it himself exactly, that there was nothing in the north for his bees to gather, since they never flew north (see Bethe's following conclusions). In that case the town (Strassburg) must spread out northward from the place of Bethe's investigations. Bethe supposes that the town remained "unknown" to the bees.

"The garden of the Physiological Institute in which my bee-hives stand lies close to the town wall. The wall is covered with green, and behind it stretch great blooming meadows which teem with bees. On the other side of the Institute lies the city. There are very few and very small growing plants in the city; and, in spite of many searches, I have only once seen bees in the inner part of the town, on two isolated sunflowers. At all events it must be admitted that only a few isolated individuals have been in the interior of the city at any time in their lives, particularly as my bees always fly toward the south to the meadows." (Bethe, p. 86.)

I must consider these assertions also as erroneous and not conclusive, for the handler of sugar wares, honey-sellers, gingerbread bakeries, and housewives who leave sweet preserves or jars of honey in the open windows well know they have to count upon much unpleasantness from visiting bees.⁶² There is not always something to be gathered from the meadows (pause in the honey-flow, the cutting of the field); and, besides that, bees in their first flight, which is devoted to orientation, orient themselves not only toward the side of the pasture but naturally on all sides.

Bethe then let bees fly in the streets of the city, only within the short distance of 350, 400, and 650 meters from the hive, in spite of the "unknown force" which acts,

⁵⁹ I noticed that bees of one and the same hive followed both directions.

⁶⁰ I admit that the French boy learns in his lesson:

"Quand les abeilles volent en haut

Nous aurons bientôt de l'eau."

But this probably national idea is just as wrong as the one that a hard winter is to be expected if bees propolize entrances strongly. In general, many statements to be found in the literature on bee management should be taken with prudence. Safe judgments can be made only after a personal experience of many years.

⁶¹ Dathe, *Lehrbuch der Bienenzucht*, 5 Aufl., p. 34, and following, Bensheim, 1892; Berlepsch-Lehzen, "Bienenzucht," Berlin, 1899, p. 28, and following; "Bienenzeitung," 2 Ausg., Nördlingen, 1861-'62, 2 Bd., p. 3 and following; v. Berlepsch, "Die Biene und die Bienenzucht," Mühlhausen, 1860, p. 219 and following; Dzierzon, *Rationelle Bienenzucht*, Brieg, 1861, p. 36, etc.

⁶² Because of this kind of trouble, bees are forbidden in the precincts of the city of Paris. The Bw. Centralblatt, No. 19, 1899, announces: "In a small city a broker had stored comb from colonies with foul brood in a room accessible to bees. The following year almost all the apiaries of the city were infected," etc. During the dearth of nectar, specifically in Bethe's case, the flying in the town where there was always something at which to nibble might have been more vigorous than to the fields where nothing could be obtained. Moreover, Bethe himself furnishes a good reason that bees flew extraordinarily accurately through the city, for he asserts that he "had seen bees inside the city upon two isolated sunflowers." How very inquiring the bees must have been to find a single flower! We can be very sure that innumerable bees (even if not seen by Bethe) followed the same instinct which drew these sunflower visitors into the city, for there are no recluses among bees, none which separate themselves from the masses to follow a way of their own, and all possess the same kind of instincts. A single linden-tree in bloom in the city is enough to attract hundreds of thousands of bees.

according to Bethe, within a distance of three kilometers. Because, when let go, these bees found their way home just as well as those from the meadow, he decides that "there can be no doubt at all that bees find their way back to the hive, *not* by means of memory pictures" (Bethe, p. 89).

I cannot find in the foregoing the slightest foundation for this view of Bethe's. If he wishes to disprove the investigations of Romanes,⁶³ then I think the attempt is unsuccessful, for Bethe leaves to us the proving that the city has remained actually "unknown" to the bees.⁶⁴

But how is the mysterious behavior in the streets explained? We shall let Bethe speak for himself: "All bees, if let fly, go upward in a corkscrew line, then suddenly take a direction and fly off in a straight line. This happens when bees are let fly in the city streets almost always before they have reached the levels of the house roofs. It often happens at a height of four to six meters above the street level, therefore generally before they can have acquired a view of the neighborhood. Now, almost without exception, they take the direction of the Institute, where the hives are."

Before I give the explanation for this, other parts of Bethe's account continue: "Light is the incentive to flight in these diurnal animals" (Bethe, p. 83); further, "Light regulates flight."

I remember, too, in Herm. Müller's investigations that he could carry a bee in a drinking-glass, open beneath, the length of the garden without the bee flying out, for it constantly pressed to the top of the glass toward the light.⁶⁵

I slipped a bee into a reagent glass and put it upon the window-sill so that the bottom of the glass was toward the window. For eight hours the bee strove inside the glass in vain efforts to reach the light. Then it died, although it would have been easy to crawl out of the open tube and fly out of the open window.

Now, if we remember that the city lies to the north of the seat of Bethe's investigations, we shall see that the sun must be in the direction of the Institute, and the bees were let fly in "quiet, sunny weather" (Bethe, p. 87). In the darker streets, perhaps unknown to them, they tried to orient themselves by mounting in circles, just as a carrier pigeon does.⁶⁶ Then they fly instinctively toward the bright source of light (just as in a room they fly unfailingly toward the bright window) until they became oriented in familiar regions. "Light regulates flight" (Bethe, p. 83).

I, therefore, can not consider the "unknown force" and the conclusions based on it as capable of proof.

I have held to Bethe's assertions with regard to these directions. From them I understand that on one side of the Institute toward the south are the meadows; and on the other (therefore toward the north) is the city. Possibly Bethe did not liberate the bees just in the center of the city but toward the edge, so that the Institute was shifted from its southern position a little toward the west or east. Further investigations might be necessary, perhaps, to prove that these bees did not return to the hive not through the "unknown force."

We learn from Bethe (l. c., p. 87) that eight marked bees were let fly in the city

⁶³ Romanes, *Nature*, 1885, Vol. 32, p. 630, *Homing Faculties of Hymenoptera*.

⁶⁴ That Bethe's idea that bees had not been flying in the city is not at all convincing, follows from something written by the editor of "Elsass-Lothring. Bienenzüchter," Karl Zwilling, which reached me subsequently. In my publication in the "Biologischen Centralblatt" the same is given, therefore, in a later passage. I quote the following: " * * * Outside of Strassburg there are many apiaries close to the wall, the bees of which never think of flying into the city except in times when there is no forage. Then they enter the candy factory of Mr. Pale, Tiergarten Strasse, and annoy the workers as well as partake of the sweets. Even in the month of December, 1899, in the warm sunshine I observed bees flying in the middle of the city on the Kleberplatz, where hundreds of pots of flowers were displayed for sale. There they gathered honey and pollen. Every year some swarms fly into Strassburg and hang on the chestnut, linden, oak, and locust trees found in many parts of the city, and once a swarm hung on the showcases of a glove-store near the cathedral. When the trees bloom, bees fly about them vigorously. In the interior of the city there are beautiful rows of chestnuts along the Ill, rows of lindens around the Kleberplatz, etc., all of which are sought out by the bees when they are in bloom. The honey-venders and those who deal in sugar wares are not molested if they keep their wares covered. As I live in the neighborhood of Strassburg (ten minutes by rail), and have been President of the Bienenverein there for thirty years, I know the conditions exactly."

⁶⁵ Herm. Müller, *Versuche über die Farbenliebberei der Honigbiene*, Kosmos, Jahrg. 6, p. 276, 1882.

⁶⁶ H. E. Ziegler, *Die Geschwindigkeit der Brieftauben*, Zoolog. Jahrb., X. Bd., 1897, pp. 99, 278.

on a quiet sunny day at distances of 350, 400, and 650 meters from the hive. The result is as follows, from an observation of twelve minutes at the hive entrance:

Distance of 350 meters.		Distance of 400 meters.		Distance of 650 meters.	
1.	1½ min.	1.	5 min.	1.	4¾ min.
2.	2¼ min.	2.	7 min.	2.	5¼ min.
3.	2¼ min.	3, 4.	10 min.	3.	5¼ min.
4.	2¼ min.	5-8.	? min.	4.	7½ min.
5.	2¾ min.			5.	9 min.
6.	3½ min.			6, 7.	10½ min.
				8.	? min.

This time experiment alone proves that there can be no explanation for an "unknown force" which "draws to the hive like a magnet;" for if it really existed these great differences in time would be entirely inexplicable. Since there was no wind, and the sun was shining, there were no hindrances to flight, and the bees ought to have reached the hive-entrance in the shortest period and at the same time. Further, supposing the existence of an unknown force which draws bees back to the hive directly, the length of time for flight is in itself too long because bees fly very quickly. A carrier pigeon would undoubtedly cover the same distances in question under the same favorable conditions in eighteen, twenty-four, and thirty-nine seconds, if we use as proof the calculations of Ziegler on the swiftness of carrier pigeons.⁶⁷ Their flight is found to be often as swift as 1000 meters per minute. If we now take the flight of bees to be half that, 500 meters per minute (a velocity which has been directly observed by Cowan⁶⁸) then the "unknown force" should have led the bees back in thirty-six, forty-eight, and seventy-eight seconds. If we double the time because the bees in the experiment were carrying honey,⁶⁹ the time would be normally about one minute twelve seconds, one minute thirty-six seconds, and two minutes thirty-six seconds. Comparing this with Bethe's table we find a striking difference which is unintelligible if we accept the idea of the "unknown force," but this difference is easily explained if we consider that the bees had to orient themselves with their eyes, and that they at first made errors in direction so that they found the hive singly after three and one-half, ten, and ten and one-half minutes had elapsed.

Of nineteen bees which were let fly from a courtyard into the street, Bethe observed that seventeen of them ("at about half the height of the houses," "before they flew as high as the roof") "took the exact direction" for the hives at the Institute. That these bees probably followed only light stimuli in taking this direction I have said before, for that they really did not return directly to the hive is shown by the above table. If all the bees, "almost without exception," which were set free in an "unknown neighborhood" under the conditions cited, took "exactly the right direction" they would have come in very much more quickly.⁷⁰ I would here refer further to what I incidentally work out from the box experiment (see p. 25).

The "unknown force" does not lead the bees back to the hive, but, Bethe suggests, to the place where the hive stands or has usually stood. Is not this memory of location? What does Bethe understand by the "unknown force"? We receive no explanation. He thinks it is a power lying outside the bees, "which draws them to this place in space as a magnet draws steel" (Bethe, p. 93). He has made no investigations to find out whether this unknown force is connected at all with any organ of the bee.

But we shall attempt to get nearer to this mysterious power.

⁶⁷ H. E. Ziegler, *Die Geschwindigkeit der Brieftauben*, Zoolog. Jahrb., X. Bd., 1897.

⁶⁸ Thos. Wm. Cowan, *The Honey-bee, its Natural History, Anatomy, and Physiology*. London, 1890; German edition, Braunschweig, 1891.

⁶⁹ "One can not take any bees at all for this experiment; but such as come into the hive laden must be chosen, for otherwise we have no guarantee that the bees will come home by the shortest way and not go foraging first." Bethe, l. c., p. 87.

⁷⁰ The assertion that bees would fly directly to the hive, but that on the way they alighted at any time, then flew again in the direct line, is in contradiction to the habits of bees. They fly many kilometers without resting.

DISAPPEARANCE OF THE MEMORY FOR LOCATION THROUGH NARCOTIZATION.

If bees are deafened with chloroform, ether, saltpeter, puff-ball, etc., the memory for location entirely disappears. After waking from the stupor they may be taken from the hive and they will not fly back to the place in space in which they are "accustomed to find it." They no longer recognize their own home nor the place where it stands; they have forgotten everything previously known. But an animal that can forget must have possessed something to remember. The memory pictures are wiped away. We see that the "unknown force" is identical with the memory for location which builds up memory pictures.⁷¹

It is necessary to mention that bees which have been stupefied become entirely normal again—that is, they orient themselves with regard to their new home, and gather new memory pictures by which they find once more the places for nectar and pollen as well as their new hive.

Bees, therefore, have capacity for learning—a fact which Bethe disputes.

Let us look more closely at the quintessence of Bethe's investigations. Upon pages 81 and 89 he formulates the view about the "unknown force," the counterpart of which is stated in this chapter (see p. 19). On page 94 we find further conclusions in the following words: "Yet I must repeat: Bees follow a force which is entirely unknown to us, and which causes them to return to the place in space from which they flew. This place is usually the hive, but it need not necessarily be. The influence of this force reaches over a circle of only a few kilometers."

But here we have no "repetition" of what has been said, but something that, on closer examination, shows statements which are contradictory among themselves, and which contradict earlier assertions, if one takes into consideration the observations which Bethe uses in formulating this conclusion (Bethe, p. 93). We shall now look somewhat more closely at these observations.

THE BOX EXPERIMENT.

If the unknown force acts at a distance around the hive of only three or four kilometers, as Bethe asserts, then all the bees of this colony which were set free within this circle must return unresistingly to the place from which they flew which "draws like a magnet." But this is not the case, as Bethe himself proves in the experiment given on page 93. He says: "In my first experiment with letting bees fly from other places I observed the following: I placed the box, in which the bees were transported, on one of the large pieces of sandstone lying around in a stone-cutter's yard and opened the lid. The bees all flew out; and most of them, after a few circles in the air, went in the direction of the Institute. Two bees mounted to a height of about three meters, made a few circles of four or five meters in diameter, and then alighted on the box. I drove them away into the air again. They flew in large circles around it, and then again alighted on the box. Now I took the box away and put it on another stone, having driven the bees into the air once more. Both bees flew so high that I could no longer see them; but a few seconds later they sank again and gradually flew around the place where the box had stood."

We see, then, that a few bees were influenced by the unknown force, but others were not. This changing condition Bethe can not and does not attempt to explain.

That the bees alighted on the stone where the box had been (which fact Bethe tells with astonishment) is very easily understood, and furnishes further proof of the excellent sense of locality in bees, for their admirable orientation with their eyes. Bethe's objection, "if they had been influenced by chemical or light reaction, then they would have flown to the stone only two meters distant, and easily visible, on which the box was placed. But they flew back to the place from which they had flown," signifies anthropomorphism brought in in its highest potentiality. It is not possible to conclude for bees that they would look for a box two meters away, which before had stood in the other place. Their

⁷¹ I might ask our ant-investigators to take up similar experiments with ants. It would be of great interest to know whether a similar condition can be demonstrated.

memory of locality leads them with infallible certainty back to the place they had impressed upon themselves by the circling orientation.

But why did these bees not fly back to the Institute if they possess such an infallible sense of locality? For the simple reason that they were young bees which had not yet developed their orientation by flying out, or perhaps old ones that had not taken their orientation flight till to this spot. No one who is thoroughly familiar with the nature of bees can have the slightest doubt about it.⁷²

But because of these experiments and others, Bethe was forced to take this position in formulating his final conclusions: "The unknown force causes the bees to return to the place from which they flew," and, therefore, to modify his earlier declaration that they return "to the place in space where they are accustomed to finding the hive." The box experiment can not explain both the habitual return to a dwelling and a single return to a place. The return to the place from which they flew takes place in those bees which returned to the box and not in those which did not "return to the place from which they flew" but turned toward the Institute. I must confess that I find no logic in these contradictory statements.

Yet hear Bethe further: "I often repeated these experiments later. The further away the bees were taken from the hive, the fewer returned to it, the more flew back to the place from which they had flown."⁷³ I chose open fields for these experiments where there were no large objects by which the bees might orient themselves optically. The box was taken up immediately after the bees had flown out. I marked the place in the grass accurately and stepped back a few steps. The bees returned with accuracy, and made scarcely a mistake of more than a few decimeters. Many trod exactly upon the spot. Often they stayed in the air for a minute, then returned. Once I noticed a bee alight on some salvia in the meadow to take nectar there; then it flew away again and then returned to the place from which it had flown. It was most startling to me when I held the box open in the air until the bees had flown away and then stepped aside a few steps. Four or six bees, after circling in the air, returned to the very spot where I had held the box, making small circles at about the height of a man."

I can only remark here that, even if there were not objects in the meadow optically discernible to human eyes by which they could orient themselves, there may have been innumerable landmarks for bees. No one will doubt this who knows anything about the wonderful certainty (far surpassing human ability) with which bees in swift flight pick out their own homes among hundreds of bee-hives placed close together and of bewildering similarity. And if Bethe could manage without marking accurately the place "in the air" (which I must say to my shame I did not succeed in doing in my control experiments, in spite of eyes which are sharper than ordinary), then the bees might have been able to do it too. In order to give the bees the least possible clue (the height of a man) I did not stand but lay down and noted approximately the large circles of searching bees in the air in the direction of the place from which they had flown. I can, therefore, find no support in the experiment of Bethe for an unintelligible "unknown force." Moreover, a few other control experiments gave such interesting and divergent results that I must enlarge further upon them.

I let a few bees fly from a box placed on the short grass of a wide meadow, approximately five hundred meters from the apiary. I quickly stepped a few paces to one side, greatly changing my position, as I did also in the following experiments. The bees

⁷² I might point out in this connection that we see an analogous condition in carrier pigeons. In Prof. H. E. Ziegler's writing already cited, we find the following abstract, Ueber die Orientierung der Brieftauben: "After all I have read and heard of the flight of carrier pigeons, I am of the opinion that their orientation depends upon memory alone, and that it is unnecessary to ascribe it to a mysterious sense of direction." If pigeons are taken away to a place where they no longer have any point of orientation they take up various directions and some make mistakes. The fanciers' society will not undertake to send out pigeons from a distance for which they are unprepared, for in that way there is constantly a greater or less loss of good pigeons. "The pigeon-fancier drills his pigeons in established routes, and thus takes them by degrees to places further away, always in one direction." Also, pigeons can orient themselves in fog and darkness just as little as bees can.

⁷³ This statement coincides excellently with the foregoing statements against the existence of an unknown force. The logical consequence from this assertion is that the "unknown force" compels bees to fly in two different directions—to the hive and to the box; the one here and the other there. This, to be sure, can not be brought into harmony with what Bethe before considered the influence of the unknown force, nor with the assertion that the "impulse to return to the hive is the strongest of all," etc.

mounted slowly in widening circles, but keeping very low on the whole, at perhaps twice the height of a man. After a minute one bee returned to the box; in one and a half minutes, a second came. Then I drove both these off and took the box away. During the next minute none returned to the place where the box had been, but I saw a number zealously seeking, flying close to the grass in large circles, then flying a little higher. Suddenly, for some unknown reason, numerous bees in a second box under my coat buzzed loudly, and almost immediately the searching bees buzzed around me (I was standing in the direction of the wind) so strikingly that my companions beside me exclaimed, "They have heard the other bees." Although I now replaced the box to its former position it remained disregarded; but whenever we went in the near neighborhood the bees followed us, and some alighted on my shoulders, hat, and coat. When I went further away my companions were surrounded, although they had no bees with them. It is noteworthy that the bees in the second box belonged to another colony.

I shall now describe the second experiment. The other box was held up high; the inmates about thirty or forty in number circled in a small radius for a long time, then gradually made larger circles. Some worked in a more up-and-down fashion, close to the box, continually turning the head toward it, just as in the first orientation flight from the hive, about which I shall speak more in detail further on. About half a minute after I took the box and drew back quickly, trying to impress accurately on my mind the spot at the height where the box had been. Two bees appeared in a few seconds, but in a place a little to one side; and then, after making large circles, disappeared again. The chief thing to be seen was the irregular search which they all carried on together after a few minutes in ever narrowing circles,⁷⁴ apparently flying close over the ground about two meters from the place where I had stood. The bees were no longer seeking the box, but their home, the entrance of which (according to my estimate) was just at the height above the ground of the circles which they were making. I can give no other explanation for this singular phenomenon. After the bees again wandered aimlessly for some time, flying around us part of the time as described earlier, they followed us homeward for about twenty paces, then turned back. That proportionately few flew back to the apiary is explained by the fact that the bees shortly before had come from the moor, and in the cool autumn weather could hardly have flown out, so that an orientation from the apiary was not yet possible. The day of the experiment was sunny, with a moderate southwest wind.

The striking occurrence, that my companions and I were so thickly surrounded, can be interpreted in so many ways that to explain it would here lead us too far.

In the foregoing I see many proofs for the existence of memory for locality; but all these box experiments are untrustworthy, since the investigations go on under entirely abnormal conditions for the bees, and the results do not harmonize with those gained from the apiary. It seems very risky to me, therefore, to draw conclusions from them for normal conditions, since we may easily be deceived. The time of year and the weather, as well as the management of the bees, will greatly modify the results of this kind of experiments. If it is recognized how easily bees are influenced by various stimuli (e. g., shaking, cooling, breathing on them, confinement, feeding, strange strong odors, etc.), I say influenced, diverted, "confused," "subdued," "goaded on," or "calmed," then it will be realized how difficult is the interpretation of such experiments and how cautiously one must work on them.

If one ask Bethe why the unknown force acts at a distance of only three or four kilometers, we receive no explanation from him; he does not even attempt to give one. The explanation, however, is very simple. The mysterious force acts within the space in which the bees have previously taken their flights of orientation, and acts only as far as they have flown at any time and gathered memory pictures. The proofs for this are easy to bring forward. They show on the other hand that this unknown force so designated is identical with memory of location.

⁷⁴ One sees from this that bees pay attention to each other, since they keep together and exhibit the same behavior. Imitation instinct? Sense of hearing?

1. If young bees able to fly (brood-nurses), which have not yet had their flight of orientation, are let fly not far from the apiary, none find their way back to the hive.⁷⁵ It is also significant that first swarms, which are almost entirely made up of old bees, in the loss of the queen quickly re-enter the mother colony, while an after-swarm, for the most part composed of young bees, buzzes about for a long time, finally entering strange colonies.

2. If old bees are let fly at a much greater distance they all find their way back.

3. If a colony is brought from a place more than seven kilometers away, and the old bees are let fly only thirty or forty meters from their hive before they have been able to make their flight of orientation, none find their way back into the hive, supposing that (in such a short distance) houses or trees intervene between it and the place from which they were set free.

4. I had two colonies placed in the garden of the Zoological Institute in Jena for the purpose of further investigation. At the end of the summer semester of 1899 they were taken to the apiary of a bee-keeper about two thousand meters distant. Since the colonies were not stupefied, it was presumed that many of the old flight bees would return to the Institute apiary, and, for the refuge of these homeless ones, I placed a hive with some empty frames exactly where their home had stood. Many hundreds returned, which, in spite of complete freedom of flight, loitered around the empty hive uneasily for two days. They were afterward chloroformed, and preserved in formaline, for purposes of demonstration. Their memory of locality had led them back.

Naturally and easily, the varied conduct of bees in these four cases is explained if we accept the theory of an orientation with the eyes through memory pictures, while the unknown force entangles us in contradictions and inextricable mysteries.⁷⁶

It seems remarkable that Bethe attempts throughout to explain "how bees find their way home," but never how they find their way away from the hive. With regard to their finding their way back to a place outside of the hive, he says only the following (Bethe, l. c., p. 90): "The place where a honey supply has been found is again sought, I think, not because of memory of locality, but because of a reaction of the same force unknown to us, etc." Bethe here refers to the observations of Lubbock (l. c.) and Forel⁷⁷ who put down vessels containing honey, and observed that marked bees always returned to them.

Because of these assertions, Bethe's theory is still more complicated, and more difficult to understand. We must not conclude, therefore, that "bees follow a force which causes them to return to the place in space from which they flew, which place is generally, but not necessarily, the hive," for in an acceptance of this opinion the bees would have to swing to and fro like a pendulum forced always between their dwelling and the honey supply, whether there is any honey there or not. If they have flown from the hive or from the place where the honey-receptacle was, the unknown force "impels" them to return to both places.⁷⁸

⁷⁵ As is well known, young bees fly for the first time about ten to fourteen days after they emerge. During the first two weeks their existence is that of "house bees," "nurses," who perform all the house-keeping and feed the larvæ. This is, I might say, the firmly established management, from which there is no deviation. Yet we can modify this activity substantially. For example, if we form a colony of bees which have just emerged, and give it a fertile queen, brood, and frames of honey, then we would see that part of the young bees become "field bees" in five or six days, thus taking up the outside work considerably earlier, even if everything is present in the hive which is necessary for the existence of the colony.

⁷⁶ Bethe refers at different times to Fabre's investigations on *Chalicodoma* (Fabre, *Souvenirs entomologiques*: Paris, 1879; Fabre, *Nouveaux souvenirs entomol.*: Paris, 1882). Yet as early as 1895 Weismann (Weismann, *Wie sehen die Insekten?* Deutsche Rundschau, 1895, pp. 434-452), had overthrown, in a very interesting paper, Fabre's view concerning the sense of direction. Weismann comes to the following conclusions: "The only correct solution of the enigma of path-finding by *Chalicodoma* is that the insects find their way back with their eyes."

⁷⁷ Forel, *Recueil zoologique Suisse*, 1 Série, T. 4, 1886-88.

⁷⁸ If an objection were here to be made, that very probably bees are compelled by the unknown force to return to the place where honey or some stimulus is placed, just as long as the stimulus is present, and that the action of the unknown force could cease with the disappearance of the stimulus, such an exception might appear unauthorized for the following reasons: We should have two entirely different kinds of unknown forces according to this view, since the one leading the bees back to the hive, in fact, forces them to return to the place where the hive stands or no longer stands. Here the stimulus, therefore, is acting in spite of the fact that the means of stimulation have been removed. Then we should have a second force which vanishes with the disappearance of the means of stimulation. Something very different from Bethe's definition, which is not consistent, and decidedly not at all conclusive, occurs, for the observation may be made frequently that food or meal remains unnoticed, and is not

HEADS OF GRAIN FROM DIFFERENT FIELDS

COMBS BUILT CROSSWISE IN SECTIONS, EVEN WHERE
STARTERS WERE USED.

What causes my bees to build crosswise of the sections, and every way, with one inch of foundation in the bottom and three inches in the top, and fastened at the bottom and top only?

Would it do to put in full sheets and fasten at the top only, and let it hang down loose?

Hastings, Pa., June 9.

V. A. H.

[If you put in foundation starters at top and bottom we are at a loss to understand why the bees built the combs crosswise unless the fastening of the starters was so poorly done that they fell down and lay crosswise, with the result that the combs were built from them. Your bottom starters should not be more than half an inch high. This may be where a part of your trouble is.

You do not say any thing about using separators; but most producers consider it an advantage to use them—not because they prevent the building of combs crosswise, but because they prevent bulging beyond the edge of the sections. Putting in full sheets of foundation, as suggested, might help the matter somewhat.

If any of our readers have experienced similar difficulty, or if any one else knows what is the cause of our correspondent's trouble, we should be glad to have him report.—ED.]

AN ABSCONDING SWARM FROM A COLONY WITH
A CLIPPED QUEEN.

I had a peculiar experience with a swarm of bees to-day. They came off with a clipped queen. I caught and caged the queen, and the bees left without settling. I looked through the parent hive and failed to find any cell from which a young queen had hatched which might have left with them.

E. H. VINCENT.

Feyil, Okla., May 9.

[We have had reports before of a swarm absconding when it had a clipped queen in the hive; but all cases of this kind can be accounted for by a stray virgin which by mistake went into the hive of the clipped queen, or which may have hatched from some obscure cell. We do not ourselves hold the theory that bees will abscond without any thing in the nature of a queen. A swarm from a clipped-queen hive will cluster; and on breaking the cluster, and taking wing, may unite with another swarm having a virgin. If they were disposed to go for parts unknown they would leave, giving their owner the impression that they went off without any thing.—ED.]

CAPPING-MELTERS USED YEARS AGO.

After reading J. Y. Peterson's article on melting cappings, page 559, May 1, I will say that I had some experience in that line years ago. I think it was in 1886 or '7 when we had a Swiss or Gerster wax-extractor. We filled the water-chamber underneath with water, and the top part with wax or cappings, and the wax and honey all ran out together. It was made to rest on top of

the stove. We simply arranged the thing to stand on a two-burner oil-stove, and rigged up a lard-can as a sort of funnel so the cappings dropped right through into the extractor. It worked all right, only sometimes the snout would get clogged with cold wax so that we had to let it all cool together. At such times I thought it spoiled the flavor of the honey. I don't see why one of them could not be made to work all right, and no odds to anybody in regard to royalties. There were plenty of them used years ago. Some of the boys did not like the heat in the extracting-room.

EUGENE MANNING.

Trumansburg, N. Y., May 8.

[There is no reason in the world why the old-fashioned Swiss wax-extractor could not have been used in the manner described; but it would have the objection that hot steam would be enveloping the one doing the uncapping. We are under the impression that the German wax-press has been used in the same way. If any one has so used it, let him report.

This press, according to directions, is supposed to be used for holding the cappings until the basket is full. Heat is then applied to the bottom without rehandling the cappings, when the honey and the wax run out into the one receptacle. On cooling, the cake of wax may be lifted off the honey.

It would not require a great stretch of inventive genius to melt the cappings as fast as they fall into the basket; but our opinion is, without having tried it, that the work would be very unpleasant, owing to the aforesaid hot steam.—ED.]

THE DR. MILLER SPLINTS NOT SATISFACTORY.

About two weeks ago I filled up a Danzenbaker hive with full sheets of foundation, putting Miller splints on them. I put this hive under my best swarm of bees, and to-day I looked them over. I found the bees had begun on the south side of the hive and cut out all the splints, leaving the foundation hanging in long strips. They had only begun on the tenth or north-side frame; but their first work was to cut out the splints, starting at the top. I wanted to send you a photograph of one frame so you could see how it looked, but I had no film in my camera. I have had a lot of trouble with the full sheets of foundation in having it hang flat; and when I read Dr. Miller's article on splints it struck me as a good thing, and I had great expectations when I put the frames in the hive-body, as the foundation looked like so many boards. If Dr. M. can tell me wherein the trouble lies I wish he would do so. I am a novice with two colonies; and when I said above I had a lot of trouble, it was in only a comparative sense. I see Mr. Pouder, on page 699, tells how he gets frames filled without wire or splints; but it would take me a long time to get ten frames filled. I am going to try his way as soon as I open a hive. HERVEY B. JONES.

Summit, N. J.

[If there were no honey coming in at the time you put in the foundation, or if the wood splints were too large, the bees probably would do just what they did do—reject the artificial stays given them. It is our opinion, without having made a comparative test, that the bees would not have

cut the foundation in strips if it had been stayed in the usual manner with wires. Years ago, when we used wire and a folded tin bar (the latter about the size of a wood splint) the bees would sometimes gnaw away the wax around the bar when they would not cut away the foundation around the wires used in the same frame. But this gnawing around the bar occurred only when honey was not coming in, and hence we deduce the cause of your trouble. If Dr. Miller can add any light on the difficulty we shall be pleased to have him do so.—Ed.]

A GOOD PLAN FOR WATERING BEES.

I have tried a great many different plans, and I believe I have finally found one that overcomes all loss of bees, and at the same time protects them from the wind, as many bees are blown into the water, and so chilled that they are unable to crawl out, and finally perish. Try it for summer or winter. It's all right for cold spring or winter.

Dig a hole in the ground any size you may think you will need. The one I use is about 2×3 feet and about 10 inches deep, and the shape of an old-fashioned wooden butter-bowl. Make the side at or near the top very sloping; pound the bottom and sides as solid as you can; cement this all over the bottom and sides so it will be water-tight, then fill to a little above the level of the ground with brickbats, after which put in the water. At any time you wish to clean the basin out, just take a bucket of water and souse it into the basin, and all dirt or leaves will float out as the water overflows. I have one end of the basin about an inch lower than the other; the bees go down in among the bats, and are entirely protected, and suck the water from the porous brick without the loss of a single bee. C. B. PALMER.

Bradshaw, Neb., June 8.

HONEY-DEW ON BOX-ELDER AND PEACH LEAVES.

I should like to ask you a question regarding the honey-dew. My bees have been working on the box-elder and peach leaves. They seem to work almost any place on the box-elder leaves. There are little sparkling drops on the leaves, but on the peach leaves they seem to work in the cups of the leaf right next to the stem. They work on them from sunrise till ten o'clock, then from four till dark. I don't know whether it is a honey-dew or not. C. W. BARR.

Florence, Kan., April 22.

[This appears to be a pure plant exudation, and not a secretion from insects. Most honey-dews, so called, are of the latter kind. But there are a few which are the product of the leaves or leaf-stems—sometimes saccharine and sometimes of a gummy nature.—Ed.]

COMPELLED TO ABANDON SECTION-HOLDERS FOR T SUPERS ON ACCOUNT OF BEE-GLUE.

I suppose you think it strange for an old bee-keeper to change from section-holders to T tins; but here the bees glue every thing so tight that I have had a great deal of trouble to remove the sections from section-holders and separators; and as I

have only 35 colonies at present, and sell all my honey at my door (yes, and more), I have concluded to run this season without section-holders and separators, so you see the need of $4\frac{1}{2} \times 4\frac{1}{2} \times 1\frac{1}{8}$ sections to use in the $4\frac{1}{4}$ super with T tins; and by trial I find the T tins to be by far the best; for here, as the glue is so very tenacious and so plentiful, our honey is, as a general thing, not fine, but sells readily at $12\frac{1}{2}$ cts., either chunk section or extracted. S. D. RUTHERFORD.

Hot Springs, Va., May 6.

IS THE GRADING OF QUEENS INCONSISTENT?

Why can a queen-breeder have such a variety of queens, rated with a graduating price list? Is not the whole matter of grading queens very inconsistent? RALPH P. FISHER.

Great Meadows, N. J.

[We see no reason why there should not be a variety of different grades of queens. Starting with the untested we have the select and the ordinary run of them. This is multiplied by the different races. In addition to the tested we have "extra select," "select," and "plain tested," the latter grade comprising the common run. A queen may be actually select tested, but not yet a breeder; that is, she may not be able to reproduce herself in queens, either in color or characteristics. This involves a couple more grades—ordinary breeder, select breeder, and extra-select breeder. A large honey-producer could well afford to pay for a select breeder. The queen-breeder will, of course, want the very best that money will buy. The small producer might be content with an ordinary breeder; then another class does not care for a breeding queen, but wants something extra select for color, gentleness, and honey-gathering qualities. She may be a good breeder, but it would probably take a year before that fact could be fully shown. If, therefore, he would want his queen-breeder to furnish him a tested breeder, that breeder would have to have extra money, of course.—Ed.]

SWEET CLOVER—WHAT THE ILLINOIS EXPERIMENT STATION SAYS OF IT, ETC.

I send herewith circular No. 116, Illinois Experiment Station, which refers to sweet clover as one of the most useful legumes for green manuring.

I have six acres of sweet clover which was sown in 1907 with oats. It stands knee high now, and the growth would be about all a plow would want to turn under. On a portion of the piece I cut a ton per acre off from it last fall, and put it up for hay. HENRY STEWART.

Prophetstown, Ill.

WATER PAINT NOT WEATHER-PROOF.

In the April 1st issue of GLEANINGS, p. 425, F. Greiner asks for experience as to painting hives with water paint. Some seven or eight years ago I painted perhaps 100 or more hives and supers with it. Results were altogether bad. In a few months it began to chalk and powder off, and soil my hands and clothes every time I handled them. The paint may do for inside work, but it doesn't stand the weather.

Utica, Ill., April 20.

A. MOTTAZ.

SPRING FEEDING PREFERRED FOR WEAK COLONIES.

When summed up, the evidence on this matter of spring vs. fall feeding appears to show conclusively that "too much spring feeding is no good, but too much fall feeding is just right." Now, although I have no desire to set up my twelve years of experience in keeping bees for the production of section honey against the teachings of any "old-timer," I really think I will just keep on feeding in the spring until there is a better way brought out for quickly building up the backward colonies.

In this locality a colony that has come through the winter without the loss of many bees will, if it has a good queen and plenty of stores, build up; and, if allowed, it will cast a swarm before the flow. Such colonies are unmolested. From 15 to 20 per cent, however, will be found to have just as good a queen, and a hive filled with stores, and yet the bees will be weak, and will not build up if left to themselves. These can be built up by stimulative feeding. It is cheaper, and involves less labor, than spreading or equalizing brood, and is not done at the expense of the good colonies. While fall feeding will reduce the other to a minimum, honey in the hive will not cause bees to breed to their full capacity, and it can not fully take the place of spring feeding.

Fort Smith, Ark.

LEO E. GATELEY.

DIVISION-BOARDS FOR DUMMIES.

In regard to wooden dummies mentioned in Straws, April 15, I should like to ask through GLEANINGS if any of its readers have ever tried using the division-boards. They would provide room for bees to cluster between them, and would overcome the objection to using dummies under the sections.

CHAS. E. CONRAD.

Brooksville, Ky.

[We do not know that we quite understand your question. The putting-in of several division-boards a bee-space apart to leave clustering room, *a la* Aspinwall, might accomplish a little, but we doubt it. If they were slatted like a fence separator they might do some good. See Mr. Aspinwall's article in last issue, p. 758.—ED.]

WHEN THE BEES SHAKE THEIR ABDOMENS ARE THEY TRYING TO LOOSEN THE WAX SCALES?

On page 491 E. A. Newell, of Massillon, Ohio, asks the following question:

"What is a worker doing when it shakes its abdomen over the combs with a gyrating movement, doing this on brood-combs over eggs, larvae, and sealed brood?"

I became interested some time ago when, while watching this performance, I saw one of the bees pick up a small wax scale, or thin leaf of wax, after the bee with the springing motion had moved away. It struck me at once that this bee had the idea of the principle of the honey-extractor.

By holding its head still, and moving its abdomen to and fro very rapidly, or, rather, from side to side, this motion would tend to throw out the small wax scales by centrifugal force.

As the wax-pockets are on the under side of the abdomen, and open toward the "rear end," as the

Jay calls it, it would take this gyrating movement to extract the wax scales. It is not every colony that has these "gyrating bees," or at least I have not noticed it in some colonies. Perhaps they have not yet "caught on."

Stratton, Colo.

PETER BOHM.

[It hardly seems probable that bees shake their abdomens to loosen the wax scales. They may fall off, it is true, during the act. There are too many indications that go to show that this shaking is simply the means of showing that new honey or new pollen has been discovered for us to entertain the shake-off-scale theory. If any subscriber has any thing to offer on the subject we should be glad to hear from him.—ED.]

SPRING FEEDING INDUCING ROBBERING; THE USE OF ENTRANCE-GUARDS TO STOP IT.

My experience last spring and also this was that feeding either strong or weak colonies in the spring causes great danger of robbing. I lost three colonies last spring and two this year by robbers. I have been handling bees more or less the past twenty years, and I have always been successful when I used the Miller feeder in September or October.

I have lately been using entrance-guards to stop robbing, with the best of success.

Asherville, Kan.

B. F. HAFORD.

HOW MUCH SULPHUR TO USE IN FUMIGATING COMB HONEY TO PROTECT IT FROM WAX-WORMS.

Will you kindly inform me what amount of sulphur per super of sections is burned when fumigating sections containing honey? How long are the supers to be fumigated? how often in, say, three months?

J. M. ROBERTSON.

Bombo, Zululand.

[The amount of sulphur per super of sections has never been given in any printed work. It is the usual custom to put about two or three pounds in a big iron kettle placed upon a couple of bricks in a room somewhere about 8×10, in which the comb honey or combs are stored. This sulphur is ignited, when the room is closed and locked. The supers should be piled up in such a way that the fumes can gain access to every section or comb.

It is the general practice nowadays to use bisulphide of carbon in place of the sulphur. Ten or twenty supers are piled one on top of the other. Surmounting the whole pile, and in an empty super, is placed a saucer containing half a pint of bisulphide of carbon. This super is then closed, when the evaporation of the chemical will cause the destruction of any bee-moth or worms that may be in the combs. The fumes from the bisulphide, being heavier than air, settle down all through. If one has several thousand pounds of honey to fumigate in a room it may be cheaper to use the sulphur.

It will not be necessary to refumigate if the supers are kept closed thereafter so that the moth-miller can not get at them again.

If any of our readers will give us particulars as to the amount to use we shall be glad to have them do so.—ED.]

DOES CUTTING OUT CELLS TO RESTRAIN SWARMING MAKE THE BEES CROSS?

Eight days after one of my good colonies sent out its first swarm I removed all queen-cells but one. It has apparently had the desired result of preventing another swarm; but one result was any thing but desired, and that was that the bees immediately became so vicious and ugly that for two or three days it was not perfectly safe for any one to come within several rods of the hive, to say nothing of approaching within customary observing distance. They gradually became more peaceable. Is that the usual result of the operation?

One old bee-keeper tells me that, if the young queens had been killed by piercing the cells with a needle, instead of removing, the bees would have retained their good temper. Do you think that would be true? If so, why not always do it?

CHESTER G. DALZELL.

South Egremont, Mass.

[The case here cited is quite unusual. It is our opinion that the cutting-out of cells had nothing to do with the subsequent vicious temperament of the bees. It is conceivable that scattering the royal food and mutilating the brood during the robbing season might make the bees temporarily cross, but that the cutting-out of cells during the swarming should do so, hardly seems tenable. The mere poking of a hole through a cell with a needle amounts to just the same thing as tearing the cell down; for if the cell be perforated in the side the bees will finish up the work of destruction.—ED.]

A PLEA FOR NON-SEPARATOR COMB HONEY.

On page 546, May 1, you seem to be sure that the use of separators is to be commended for comb-honey production. Now, when I go into a store to sell honey I always call attention to the fact that my honey is nearly, if not quite, full weight. When I use separators or fences I always feel as though I did not care to put my name on the cases because they are so light. I have shipped tons of honey that would run from 23 to 25 pounds to the case, and it always gives satisfaction to dealers and to consumers.

Side by side in my yard I have nine-frame telescopic hives and different makes of eight-frame hives, the latter being provided with separators. I always feel sure of getting more sections in the nine-frame hives, where the separators are not used, and the sections are also nearer full weight. I think that, without the separators, the bees have a better chance to work, although the greater yield of honey on the nine-frame hives might possibly be accounted for by reason of the extra frame or because of the telescopic cover which I use on those hives. I have taken first premiums at State, interstate, and county fairs, competing with the product of thousands of colonies where separators were used.

CHARLES W. SAGER.

Mabton, Washington.

If you will refer to what we have said on this subject you will see that we have never claimed that *no* bee-keeper can produce good marketable comb honey without separators; for it can not be denied that there is occasionally here and there one who can produce fine comb honey without separators; but he is the exception that proves the

rule. But the average man in the average locality should be discouraged in the most emphatic manner from making any attempt at it.

The great bulk of the non-separated comb honey that has been shipped out has done more to hurt the markets, if we except dishonest grading, than any other one thing. Those of us who visit the large centers and look over the lots of comb honey that come in find that the average lot of sections produced without separators is a bad mess. It should never have left the locality in which it was produced. About all that can be done with it is to cut it out of the sections, pour a little extracted honey over it, and sell it for chunk honey at a low price.

The fact that the Colorado Honey-producers' Association are now discriminating in their grading-rules against an article produced without separators, and the further fact that the great majority of bee-keepers do not attempt to work by that plan, should be sufficient warning to others not to try it.

That more honey may be produced without separators may be so; but the average bee-keeper can not afford to spoil the markets, even if it is true.—ED.]

WHY THE BEES DON'T GO INTO THE SUPERS.

I have two hives of bees that completely refuse to go up into the supers to work. They have an abundance of stores below, and plenty of brood, the brood covering three-fourths of the frames. I have tried to coax them up by taking two frames of honey half drawn out, bees and all, and putting them in, but it didn't do any good, so I resort to you for instruction.

I. B. MITCHEM.

Newburg, Ind.

[There are two reasons to assign why bees may not go up into the supers: too light a force of bees, or too light a flow of honey, or both. The remedy is to have strong colonies for comb-honey production. Of course, if the honey-flow be not strong they will not enter the supers and store honey, unless the light flow continues for a considerable length of time; but in the meantime they may swarm, for a light flow is more conducive to swarming than a heavy one. It is advisable to look through the hive, cutting out any swarming cells that may be found on the combs; give a large entrance, not less than $\frac{3}{4}$ deep by the width of the hive, and see that shade is provided during the hottest portion of the day, say from ten o'clock on to three in the afternoon. If there be no shade it would be advisable to put a shade-board projecting front and rear and over on the south side, so as to shade the hive during the hot part of the day.—ED.]

SUCCESSFUL WINTERING OF TWO DANZENBAKER HIVES PACKED IN PAPER.

Last fall I had two swarms in Danzenbaker hives, and no suitable cellar in which to put them. I bought the thin super covers and deep telescope covers. On top of the super cover I laid newspapers, letting them hang down all around until there were about 100 layers on all sides and ends. The telescope covers were then slid on and left for the winter. Entrance was smallest on the Danzenbaker bottom-board, and sheltered by a piece of board set in front under

outside cover so the sun's rays could not strike the entrance. The bees wintered finely; and when I removed the covering early in May the brood and pollen were plentiful. I did not use a super.

HERVEY B. JONES.

Summit, N. J.

DOES NOISE OF ANY KIND HAVE ANY EFFECT IN BRINGING DOWN SWARMS?

This morning the second swarm of the season came out. It went very high, and I was afraid it would alight on a tall tree. My son blew his cornet, and they came down and alighted in three different bunches. In a few minutes one bunch divided and joined the two other clusters. They all came from the same hive. Do you think there could have been two queens? We had a hard time in getting them down, as they were in a brushy place: HATTIE E. GRAVES.

Walpole, N. H., June 9, 1908.

[The blowing of a horn or trumpet would not, in our judgment, have any effect upon the swarm while in the air. It has been said that the noise drowns the note of the queen, but we doubt it. The swarm in this case clustered because it would have done so any way. In all probability there was one or more queens, and this was the cause of the separate clusters, otherwise they all would have clustered in one spot or gone back to the parent hive.

It sometimes happens that, when two or more swarms come out, there will be a division of the bees and a general mix-up. From what you write, we take it that there was only one swarm which divided as explained.—ED.]

CATCHING A SWARM WITH THE QUEEN ON A POLE.

A friend of mine had clipped his queen's wings, and when the colony swarmed he found the queen. He picked her up and put her on a forked stick. He next went into the big field where they were all scattered, and held her up; and every bee came and lit on the pole.

Sandy Spring, Md. JACK BENTLEY.

[It would be perfectly feasible to have a swarm in the manner related in your letter. This has been done; but the usual rule is to put the queen in a cage, fasten the cage to a pole, and then place the pole where the bees are flying the thickest.—ED.]

DO COLONIES WITH MANY DRONES PRODUCE THE MOST HONEY?

I have noticed that the hives that raised no drones to speak of store but little honey, and that the hives that raise considerable numbers of drones store the most honey. Of course if the drones are too numerous, they consume considerable honey; but even if there are a large number, the hive stores more than hives having but few drones. I am speaking of colonies that are about equal in strength of worker bees.

I have thought sometimes that the presence of a considerable number of drones in a hive encourages the bees to work harder, or that the drones help in some way—perhaps by keeping up the warmth of the hive, if in no other way. If a drone is held in the hand he feels quite

warm, and no doubt throws off a good deal of heat in the hive.

E. E. WAITE.

Mystic, Conn.

[That the drones throw off bodily heat which is useful in keeping up the temperature of the supers is generally believed; but that the best honey-gatherers are those that have the most drones may be true of blacks, hybrids, and Caucasians, but we think is not necessarily true of Italians.—ED.]

HOW ARE SECTIONS CLEANED RAPIDLY?

In GLEANINGS for Dec. 15, 1907, page 1597, is an article by F. J. Farr, of Longmont Colo., on cleaning sections. He says he knew a Mrs. Marian Fuller, of Beloit, Wis., who cleaned and packed 125 cases of 24 sections each, between 7 and 5 o'clock, which is 9½ hours, taking half an hour for dinner. This would be cleaning and packing 3000 sections in 570 minutes, or nearly 5½ sections a minute. We have no slower or more tedious work than cleaning honey. I can at best clean only about 15 cases in a day. The fastest cleaner I have heard of in this part of the country claimed to have cleaned 20 cases in a day. If Mr. Farr will tell us how we can do the work more rapidly he will confer a great favor upon comb-honey producers.

MISS WILLIE WHITE.

Fallbrook, Cal., Dec. 28, 1907.

[Perhaps the style of super or section would have something to do with the extraordinary speed, or possibly the propolis was not as abundant in the one case as in the other. At any rate, we should be glad to hear from any of our readers on the subject.—ED.]

THE CHITTIM-TREE; A WESTERN HONEY-YIELDER.

While the bee-keepers of the East are casting about for a tree that is valuable otherwise than for honey, I should like to call their attention to the chittim (*Cascara sagrada*) that grows plentifully here in the coast country, and is considered a good honey-producer. All know the value of cascara bark, and the wood makes a fence-post equal to black locust. The tree is of small growth. Eight to ten inches in diameter is considered a large tree. It remains in bloom a month, and is visited by the bees from the first out in the morning to the last ones at night. It has been in bloom for two weeks, and the bees are filling the sections with chittim honey.

Halsey, Oregon, May 24. J. WADDELL.

BEEES THAT CAP HONEY WATERY NOT ALWAYS BEST.

In answer to your footnote, page 431, April 1, I will say I have often had Italians cap the sections watery; but they were medium, to the poorest honey-gatherers—never among the best.

Corinth, Me.

S. W. CRESSY.

YELLOW SWEET CLOVER; A GOOD YIELD FROM IT.

Bees are doing very nicely, and are well along with the second super. There seems to be nothing doing in white clover, but a fine yield from yellow sweet clover now blooming.

Brooksville, Ky., June 12. E. E. CORLISS.

OUR HOMES

By A. I. Root

Whatsoever a man soweth, that shall he also reap.—GAL. 6:7.

Some years ago there were several bright articles in GLEANINGS, or some other of the bee journals, signed "B. Lunderer;" and I have been wondering whether B. Lunderer were still alive. May be Dr. Miller can tell us something about it. Well, if he is alive I want to ask his permission to sign myself just now B. Lunderer, or, to be more exact, I guess it had better be Seedcorn B. Lunderer; or may be we had better cut it short and say Blunderer, for that is just what I am. I have been feeling guilty for some days past to think that, with all my exhortations and teachings, I have been making such blundering work of planting our cornfields. We shall have to go a little back in order to get in the whole lesson that comes from my blundering.

Two years ago, after listening to Prof. Holden, and reading up in regard to seed corn, I selected at husking-time about 200 ears of corn, strung them on a wire, and hung them up in our cellar basement near the steam-pipes. Then I told you about how I took six kernels from each ear and planted them in the greenhouse. The ears were all so uniformly good that there were really none to throw out. Well, I have told you about our splendid corn crop of last season, that even Prof. Holden, when he went through it, admired. There was only one trouble with it. In consequence of the prolonged wet weather in the spring of 1907 we could not get our corn in until far along in June, and as a consequence a great deal of it was not perfectly matured before frost. Well, Prof. Williams, of our Ohio Experiment Station, gave us a talk last fall, just before corn-husking time, and admonished us to secure our ears for seed corn from some hill that had *four good stalks*. His argument was that we want to select our seed from a plant that had such strong fertility and vigor that it made a good ear in spite of the competition of the three other stalks. For instance, if you go to the corn-crib and select your nicest and best-matured ears you will be more than likely to get ears that come from a hill where there was only one stalk. Any sort of corn-plant would make a large nice ear where it had the whole hill by itself; but we want to get our "pedigree strain" from plants that have enough vitality to stand crowding—not from one that has made a good ear (or a couple of ears) because it has a better environment. This matter has been much talked about, and I suppose you all know more or less about it, and I hope your practice is according to your knowledge. Let me digress a little right here.

Poultry-men are anxiously inquiring why so many chickens die in the shell, and also why so many eggs will not hatch at all. The answer seems to come from a great number of experts, that we want stronger fertility. The eggs must be, as many as possible, fertile, of course; but we want the very strongest fertility. We want to be sure that both parents are in the best of health, and lack nothing in the way of the best kind of food, exercise, air, quarters, and every thing else. When you get a strong vigorous vitality and fer-

tility, then your plant, or chicken, will make its way in spite of bad weather or uncongenial surroundings. This thing applies not only to corn but to the seed of every thing a farmer raises. One of our experiment stations sorted out the largest beans and planted them by themselves; then they put side by side the smallest beans, and they tried this with many kinds of garden seeds. The large well-developed seed that gives the little plant a good send-off might produce double the crop of the small one. Inherited vigor and vitality run all through the animal and vegetable kingdom—"Whatsoever a man soweth, that shall he also reap."

Well, now, friends, I am first-rate "on a talk," am I not? I have given you some grand articles and some grand exhortations about saving your seed corn; but after all I fear I have been like a guidepost on a country road, which continually *points the way*, but never goes *anywhere* itself.

Let me tell you what I did after listening to Prof. William's grand lecture on selecting seed corn. He said you had better make selections of ears you want to use, before the corn is fully matured; and he thought it rather better to let the ear remain on the stalk until husking-time. You are aware, perhaps, that, when corn is a little late in maturing, the juices and nutriment in the stalk go into the ear after the corn is cut, especially if it should be cut early to avoid frost. For this reason he said he would tie a colored string or tape to the stalk selected, or clip off the tassel from all stalks where they would be saved for seed.

Well, we not only had trouble (a year ago) in planting our corn on account of wet weather, but the blackbirds and cut-worms destroyed so much of it that we planted a second time and some of it even a third time. On this account it was a little difficult to select the best ears in a field of half a dozen acres. Before I went to Florida I had a good man go through and clip the tassels from enough stalks to give us plenty of seed. Then I directed that, when these ears were husked, they should be placed in our slatted potato-boxes and be hung up by four wires near the steam-pipes in the basement. And this was done; but instead of having half a dozen crates of seed corn, when I returned home in April I found there were only *two* crates, and these not quite full. The explanation given was that some hands were taken out of the factory to help do the husking when the weather happened to be just right. Well, these new comers, I am told, absolutely *refused* to watch for the stalks with the tassel clipped off. They said the best way and the proper way to select corn was to pick it out of the crib, regular old-farmer style. With all my blunders, perhaps it does not become me to complain of the stupidity or stubbornness of the average farm help; but it really vexes me, when I take the trouble to explain why I want seed corn saved up by itself, to hear men of average sense and intelligence say they "do not have time" for any such fussing. Prof. Holden tells us about addressing a great audience somewhere in Southern Ohio. After he had spent an hour or more in making all of these things perfectly plain, a big pompous man came up and said in substance, "Prof. Holden, I have been very much interested in your talk; in fact, I have greatly enjoyed it. But I

grow corn by the *hundred acres*; and you know, of course, where I do business on a large scale like that I can not stop to fuss with the things you have been talking about."

Our bright and genial friend Holden said that *that* speech actually made him mad. "Can't stop to fuss! indeed!" Well, now, listen to what I am going to tell you. When I got back from Florida I was all taken up with chickens and the chicken business. I seemed to have lost interest and enthusiasm for the corn business. I advised and directed a little about getting the ground ready, and somehow got it into my head that those two boxes of corn would plant our fields; and as the seed corn kept all winter by the steam-pipes grew so finely the year before, I did not even take the trouble to test the ears. All at once the weather turned favorable, and the men were ready to plant the corn; but when it was half planted I woke up enough to see that our supply would plant only half the field. Then I told the men they would have to select enough to finish it, out of the corn-crib in the way farmers usually do. But one or two of them said that, in consideration of the whole crop being late, and much of it not fully matured, they would hate to risk that in the corn-crib without testing. Now, I could just as well have selected good ears from the crib, and tested them in the greenhouse, as to spend my time in fussing with things of comparatively little importance. But the time to plant was upon us, and it was not done.

A few days before, when buying some baby-chick food of our local seedsmen I saw on the counter a box of corn-plants, all thrifty, and apparently every seed making a good strong plant. I decided, rather than to risk the corn taken from the crib, I would *buy* some corn to finish the field. I did not take the time or trouble to ask if he still had some seed like that which produced the box of plants on the counter. I simply asked for a bushel of his "best seed corn." I paid him \$2.00 for it. When I gave the men that bag of seed corn my conscience began to trouble me a little. I hastily took ten kernels out of the bag, and then got ten more, such as we had planted of our own, and put them in the greenhouse. In about 40 hours every grain cured by the steam-pipes started to grow, but not one grain from that out of the bag. At the end of 60 hours there was a good strong shoot from every kernel of our own growing; but only half a dozen had started at all, from the corn out of the bag. The other four rotted. The corn out in the field did just the same way. It was all late in starting, and only about half of it grew at all. I reported at the seedstore in order that they might know about it, and stop selling that seed to anybody else. Their explanation was this:

Their own tested corn was sold. This they bought of a good reliable farmer. He assured them that he and his neighbors had both planted it, and that it was already up nicely when he offered the seed for sale. Now, there are two and possibly three explanations to this. First, the "reliable farmer" may have put six or eight grains in a hill, so that if only half of the corn grew he would still have a fair stand. I wonder how many farmers work in this way. We adjusted our planters so as to have from three to five grains in a hill.

Another explanation may be that the corn that grew all right or very well at early planting time would only half grow at late planting time. I am told this often happens with corn cured in the ordinary way in the crib.

Now, you would probably suppose that, when I found only about half of the planting would grow, I would have immediately selected ears from the corn-crib, tested them in the greenhouse, and had them ready to plant from tested ears only, when we came to plant over again. Well, I did not do it. I think I must have gotten a fit of being lazy or shiftless, for I was not particularly busy. When I came to look at the stand of corn I told the men to go right at it and plant some more, not only at every missing hill but where there was only one stalk; and I went and picked out some of the best ears in the corn-crib for planting over. One of my men, however, who had had much more experience with seed corn than I have, threw out about half of my selection; and in order to test my ability to pick out good ears of corn that would grow, I selected two ears that I considered as good as any in the crib. Then I took ten grains from each which I put in the greenhouse in rows, the two rows being only an inch apart. Now listen to what I am going to tell you. Every kernel grew from *one* of those two ears, and every kernel *rotted* from the other one. Perhaps I am a poor hand at selecting seed corn; but I am of the opinion there are other bunglers besides myself. After my experiment I took the ears and carried them to Mr. Weibly, and said, "Mr. W., every grain of corn grows from one of these ears, while every one rotted from the other one. Now, can you tell which ear is the good one and which the bad?"

He told immediately, and explained it by saying one ear showed slight traces of mold. Before this, I showed both ears to Mrs. Root. Her father used to be great on corn and saving seed corn. She called the bad ear the better one of the two. Now, you may think this is a trifling matter; but suppose a farmer in picking out ears from his corn-crib, to plant, makes such work of it as I did. Suppose he gets hold of just *one* ear that does not contain a grain that will germinate. What is the consequence? Why, a great part of his crop will be knocked out unless he replants as we have been doing, and replanting is poor business as a rule. If he does not replant, there will be a lot of hills with only one stalk and possibly two, and sometimes a big lot without any in at all; yet he goes through all the motions in getting a crop, cultivates his ground both ways with a patent cultivator, and does splendid work, using a team that costs just now perhaps four or five hundred dollars; and yet I had not enough energy or enthusiasm to give the men plenty of *good seed* that I *knew* would grow, without any guesswork about it.

May be some of you wonder what this seed-corn business has to do with the Home papers. Well, friends, it is not only the corn crop and the crop of chickens and horses and cattle, but it is the crop of *boys and girls* that may be injured or led to go astray by just such slipshod methods and such procrastination as I have been telling you about. I have a nice little greenhouse, warmed by exhaust steam — the best place to test seed corn in the world, and yet at three different

times I delayed and neglected to take the precautions that I knew *ought* to be taken. The most of you have boys and girls growing up in your homes (or if you have not, you *ought* to have); and it is just as important that you be up and dressed, and ready to take the lead, as it is important for you to have your seed corn ready. Sometimes the younger ones around here say something like this:

"Why, father, there is no need for *you* to fuss and worry about the corn crop. We have experienced men who know how to do it all right; and you do not need to pay any attention to it unless you feel like it," etc.

Well, now, this is bad advice. My very health depends on my being busy about something; and it is my business to be busy about something that ought to be attended to, rather than something that I "feel like" doing. As fathers and mothers (at least most of you are), why are your boys and girls not going to church and Sunday-school? Talking to these young people about it is all right; but to make a success of raising children (as well as corn) you must be right in the business yourself. Go to church yourself and set an example; and go to Sunday-school also to set the example before the children and grandchildren. Nothing else will do the business. I explained to the men the importance of saving the seed as I have told you. But I ought to have been out in the field myself to *see* that all the help that was sent out to assist in husking the corn obeyed orders to the letter, no matter whether they thought I had peculiar notions or not;* and just the same way with your boys and girls. There are plenty in almost every neighborhood who are just beginning to inquire into things. Satan works every day in the week, nights and Sundays; and if you do not sow good seed he will get in *his* sort of seed. Remember what I have been telling you—"Whatsoever a man soweth, that shall he also reap."

"CABINS IN THE WOODS" NOS. 1, 2, 3.

I suppose most of our readers remember about the cabin in the woods up in Northern Michigan—the house that was built in one day with lumber that was brought in one load by one team of horses. Most of you have probably also read about the cabin in the woods No. 2, down on our "Robinson Crusoe island" in South Florida; and I now take pleasure in giving you a picture of the same—see page 818.

The picture does not give as much of a glimpse as I could wish of the tropical plants—palms, palmettos, different kinds of cacti, and of the rubber tree, that grows naturally just at the right of the building. You get a very good view of the gnarled and twisted live oaks. The one on the left is a curiosity, and many people come to see it. Two pretty good-sized oak-trees are united by a large limb or tree-trunk that reaches across from one to the other; in fact, it makes a very nice seat where a dozen can sit down in the shade.

*As the matter has turned out, it would have been money in my pocket to pay \$10.00 a bushel for the ears that those huskers refused to save out from the stalks having the tops clipped off. The damage to my crop will probably be a great deal more than that in spite of all that can be done now to make up for the mishap.

Various speculations have been made as to how it came about. I think most likely that the tree tipped over when it was young. One of the branches came down to the ground and took root. Then shoots shot up, one from this branch and one from the root of the tree. When these shoots each became large trees, a horizontal trunk nearly a foot in diameter was left bridging over the space from one tree to the other.

In the foreground you can get a glimpse of friend Shumard's queen-rearing hives. Off at a distance, back of the house, is the Gulf of Mexico, that makes itself heard if not seen almost every hour of the day. I found the booming of the breakers was a fine thing to lull me to sleep when tired.

The washtub on top of the barrel was put there to get it out of the way of the chickens. When neighbor Shumard and I were both in "the chicken business" every thing had to be elevated or fenced in to be safe from their depredations. Perhaps I should explain that cabin No. 2 cost about \$200. It took rather *more* than a wagon-load of lumber; but every thing, including the doors and windows, was brought in one load by a sail boat called the Phantom. Perhaps you may wonder how I manage to build so many cabins. Well, this one was built with the understanding that, when I got through with it, friend Shumard was to take it off my hands at half the original cost.

On page 818 you will find a picture of our last cabin in the woods. Mrs. Root, however, objects to calling it a "cabin." She says she thinks it deserves the name of "cottage in the woods." The people standing out in the front porch are your humble servant, Mrs. Root, and Mrs. Brewer, the good wife of the friend (M. L. Brewer, Philo, Ill.) who kindly furnished me the pictures. In Florida the houses are all up on brick piers or piers of some kind. It seems to be necessary for health, and to preserve the timber, to get it a certain distance above the ground that is so damp a good part of the year. Usually the air is allowed to circulate freely under the building. Mrs. Root objected to the untidiness of such an arrangement, so we had latticework put up. You will notice one part of it has tumbled down. You will notice also the long-leaf pine-trees in the background and at either side. These had to be cut away to make room for the house.

Mrs. Root is great on lawns—green lawns. She says she can not admire flowers or shrubbery without green for a background; or perhaps, rather, for a foreground. Well, we got our lawn well started by taking up clumps of Bermuda grass out of neighbor Rood's field. It is tremendous stuff to grow where you do not want it. Our boy Charley graded and leveled the dooryard and marked it off in furrows about two feet apart. The grass was then torn to pieces, thrown into the furrows, and covered up. But even though we had almost no rain for five or six weeks in February and March, nearly every spear of grass started. The chickens admired the grass as much as we did, or more, and we had a long fight to make them let it alone and stay in their own place down in the back yard. We planted quite a lot of shrubbery purchased of the Reasoner Brothers, of Oneco.

At the right you will notice a very pretty

golden-leaved arbor-vitæ, and surrounding it is a circle of hibiscus. The latter grows with wonderful luxuriance all over Florida. Mr. Rood had one little bush, set out, I think, in September, and it commenced putting out blossoms in November and kept it up all winter long, and it gave him from one to three great beautiful blossoms, opening continually.* The house well painted and finished outside, with plastered walls inside, etc., cost about \$1000, including eave-spothing. A cement cistern on top of the ground reaches up to the eaves of the porch. This cistern is under the roof of the porch at the back side of the house.

Now just a word in closing about the expense of building in Florida. The cottage on the island was built by brother Shumard and his son-in-law. I paid them \$2.00 a day. This last one was built by men who worked only eight hours a day and got \$3.00. Now, in plain regular work they accomplish a great deal, and *perhaps* earn their money; but where we pay such prices as these you can not afford to keep your carpenter at little tinkering jobs. As most kinds of furniture are rather expensive in Florida, you will decide, perhaps, after getting the prices, that you can make stands, tables, etc., cheaper than to buy them ready made. Well, this is all very true if you do the work yourself; but when you set a carpenter at work on something he is not used to, at almost 40 cents an hour, you may find your home-made table and stand will cost you more money than you would have to pay for something a great deal nicer at some furniture store.

THE WRIGHT BROTHERS AND THEIR FLYING-MACHINE; ALSO SOMETHING IN REGARD TO OTHER FLYING-MACHINES.

If you want the full particulars of all that has been done by the Wright Brothers and others in America, as well as every thing that has transpired up to date in the whole wide world, you should subscribe for *Aeronautics*, published at 1777 Broadway, New York. The price is \$3.00 a year; but if you do not wish to subscribe for a whole year you should at least get the anniversary number for June, 1908. It is quite a good-sized magazine, and perhaps the most up-to-date document that has appeared on the subject of aeronautics.

The most valuable point to me in this number is the first article, which is a communication from the Wright Brothers themselves. After giving a schedule of every flight during May, 1908, they add as follows:

Our recent experiments were conducted upon the grounds near Kitty Hawk, N. C., where we experimented in 1900, 1901, 1902, and 1903. The flyer used in these experiments was the one used in making the flights in September and October, 1905, near Dayton, Ohio. The means of control remained the same as in those flights, but the position of the controlling levers and their directions of motion had to be altered in order to permit the operator to take a sitting position. A seat for a passenger was added. The engine used in 1905 was replaced by a later model, one of which was exhibited at the Aero Club Show at New York in 1906. Larger gasoline-reservoirs and radiators were also installed.

We undertook these experiments in order to test the carrying capacity of the machine, and to ascertain its speed with two men on board, as well as to regain familiarity in the handling of the

machine after a period of almost three years without practice. No attempt was made to beat our record of distance made in 1905.

The first flights were made over a straight course against winds of 8 to 18 miles an hour. The equilibrium of the machine proving satisfactory in these flights, we began to describe circles, returning and landing at the starting-point. These flights covered distances of from 1 to 2½ miles.

On the 14th of May a passenger was taken on board. In the first flight the motor was shut off at the end of 29 seconds to prevent running into a sand hill, toward which the machine was started. But in a second the machine carried the passenger and operator for a flight of 3 minutes and 40 seconds, making a circle, landing near the starting-point. The wind, measured at a height of 6 ft. from the ground while the machine was flying, had a velocity of 18 to 19 miles an hour. The distance traveled through the air as registered by an anemometer attached to the machine was a little over 2½ miles, which indicated a speed of about 41 miles an hour. A speed as high as 44 miles an hour was reached in an earlier flight, with only one man on board.

In a later flight, May 14, a false movement of a controlling lever caused the machine to plunge into the ground when traveling with the wind at a speed of about 55 miles an hour. The repairs of the machine would have necessitated a delay of five or six days; and as that would have consumed more time than we had allowed for the experiments we discontinued them for a time.

Besides this there is quite a long article by Byron R. Newton, correspondent of the *New York Herald*. From his account I extract as follows:

When the little band of correspondents arrived at Manteo they decided to feel out the ground by sending one of their number to ascertain if there was any change in the Wrights' policy of secrecy. It was a day's journey, and a fruitless one. When the scout reached the aerodrome, nestled between Kitty Hawk and Kill Devil Hills, the Wrights were about to make a flight; but at the approach of a stranger they wheeled the aeroplane back into the building, closed the doors, and advanced to meet their visitor. They were civil, but very firm. "We appreciate your good intentions," they said, "but you can only do us harm. We do not want publicity of any sort. We want to go on with our experiments; but so long as there is a stranger in sight we shall not make a move. Come back a month from now and we will show you something worth telling to the world. At present we are simply experimenting with new features of our machine."

Then one of the brothers and their assistant mechanic walked with the correspondent back to his boat and watched it far out on the sound toward Manteo.

The next morning at 4 o'clock, equipped with a guide, water, and provisions we set out determined to ambush the wily inventors and observe their performance from a hiding-place in the jungle. After a tedious journey over sand hills, through long vistas of pine forest, and through miles of swamp and marsh land in which two of the men narrowly escaped the poisonous fangs of moccasins, we found a spot opposite the aerodrome, commanding a clear view of the beach and sand hills for a distance of five miles in either direction. There for four days we lay in hiding, devoured by ticks and mosquitoes, startled occasionally by the beady eyes of a snake, and at times drenched by heavy rains. But it paid. We saw what few human eyes had ever witnessed before, and had the satisfaction of telling the world about it.

Often we wondered if those men ever slept. They were at work before the sun came up; they frequently made flights in the early twilight, and lamps were flickering about the aerodrome until late in the night.

The first flight we all witnessed was made early in the morning. As we crept into our hiding-place we could see that the doors of the aerodrome were open and the machine standing on its mono-rail track outside. Three men were working about it and making frequent hurried trips to the aerodrome. Presently a man climbed into the seat while the others continued to tinker about the mechanism. Then we saw the two propellers begin to revolve and flash in the sunlight. Their sound came to us across the sand plain something like the noise of a dirigible balloon's propellers, but the clacking was more staccato and louder. The noise has been described as like that of a reaping-machine, and the comparison is a very good one. We were told by a mechanic who assisted the Wrights that the motor made 1700 revolutions a minute, but was geared down so that the propellers made but 700 revolutions.

For several seconds the propeller blades continued to flash in the sun, and then the machine arose obliquely in the air. At first it came directly toward us, so that we could not tell how fast it was going except that it appeared to increase rapidly in size as it approached. In the excitement of this first flight, men trained to observe details under all sorts of distractions forgot their cameras, forgot their watches, forgot every thing but this aerial monster chattering over our heads. As it neared us we could plainly see the operator in his seat working at the upright levers close by his side. When it was almost squarely over us there was a movement of the forward and rear guiding-planes, a slight curving of the larger planes at one end, and the machine wheeled about at an angle every bit as gracefully as an eagle flying close to the ground could have done.

It appeared to be 25 or 30 feet from the ground; and, so far as

* Beautiful and luscious mulberries also grow with wonderful rapidity and luxuriance. Cuttings stuck in the ground at the proper time of the year will take root and send up great shoots in a wonderfully short time; and sometimes you will get some pretty fair fruit the very first year.

we could judge by watching its shadow sweeping along the sand, it was going about 40 miles an hour. Certainly it was making the average speed of a railroad train.

After the first turn it drove straight toward one of the sand hills as if it were the intention of the operator to land there; but instead of coming down, there was another slight movement of the planes and the machine soared upward, skimmed over the crest of the mountain, 240 feet high, and disappeared on the opposite side. For perhaps ten seconds we heard indistinctly the clatter of the propellers, when the machine flashed into view again, sailed along over the surf, made another easy turn, and dropped into the sand about 100 yards from the point of departure. No sooner had it touched the sand than men started from the shed with two wide-tired trucks. These were placed under the machine, the motor started, and the aeroplane at once became a wind wagon, rolling itself back to the starting track with the power of its own propellers. After each flight all the mechanism was examined in most painstaking manner, and the operator always came down when the slightest thing about the machinery was found to be working imperfectly.

On several occasions we saw the machine sail straight away up the beach until it was a mere speck, scarcely distinguishable from birds and other indistinct objects near the line of the horizon. During these flights the sound of the propellers would be lost altogether until the machine turned about and came back, frequently landing within a few feet of the starting-point. These long flights must have covered a distance of four to six miles.

As our readers may be curious to know many men at the present time have actually been able to fly without the aid of a dirigible balloon, we give the following:

THE SEVEN MEN IN AMERICA WHO HAVE FLOWN IN MOTOR-DRIVEN AEROPLANES.

Wilbur Wright, Orville Wright, A. M. Herring, Thomas Selfridge, F. W. Baldwin, G. H. Curtiss, J. A. D. McCurdy.

Mr. Curtiss, so far as we can find out, has flown a greater distance—1020 feet—on first trial than any other aviator in the world. The time was 19 seconds.

Last, but not least (in my opinion) I hold in my hand a card postmarked Montaigne, Paris. Underneath the picture of L'Arc de Triomphe there are just five words that I prize very highly. These words are, "With kind regards, Wilbur Wright." I prize them because they remind me that my good friend Wilbur Wright, even if he is "away up in the air," and traveling all over the world, still remembers his old friend A. I. Root.

POULTRY DEPARTMENT

HOPPER FEEDING, ETC.

So far in my poultry experience I have been in the habit of letting my fowls, old and young, help themselves to their rations. Even if it were true that there are advantages in feeding only at certain times, and just what the fowls pick up clean, it would be very inconvenient for me to be around at these regular periods; and I have had such good success by keeping the food constantly before them, or where they could get it when wanted, that the saving in labor to me is worth more than the extra feed required by hopper feeding; and I am sure that none of my poultry, either young or old, ever suffer, even a few hours, from a lack of food. There is, however, one great objection to this manner of feeding. The sparrows, robins, blackbirds, and other songsters, soon "catch on." I thought I had circumvented them by having the feed in a pen of poultry-netting, and letting the fowls get in and out by an underground tunnel. But the birds soon learned to use this tunnel almost as well as the chickens. Just while I write, it seems as if all

the birds in the vicinity had discovered that we not only have a large mulberry-tree, another one of early sweet cherries, but also *wheat and corn ad libitum* to fatten the birds and keep them in good cheer. I have circumvented the birds for a time, but I do not know how long it will work. The food is all placed upstairs in that little house shown on page 638, May 15. If the birds do find their way upstairs, as the chickens do, the sight of the blue sky through the poultry-netting above their heads prevents their getting out the same way they got in. I have not yet decided how to dispose of the birds that have got caught under the poultry-netting. It seems too bad to kill the little fellows, and Mrs. Root suggests that it is against the law to kill song birds. Of course sparrows can be disposed of; but I find quite a lot of other birds helping themselves to the wheat and corn provided for poultry. I have not looked up the law in regard to the matter; but I can not for a moment think that the farmer or fruit-grower is prevented from killing birds that are destroying his crops. We have a large mulberry-tree that bears great quantities of mulberries; but we have had scarcely a ripe berry here in the North for several years past, because the birds get there before the fruit is fairly ripe. This year we succeeded in getting a few nice early cherries before the birds found out *where* they were and how *good* they were.

HENS LAYING BETTER WITHOUT MALE BIRDS.

The *American Poultry Advocate* for June says that the Geneva, N. Y., Agricultural Experiment Station made some experiments in keeping laying hens with and without a male bird. This bulletin, in closing up its observation, makes the following statement:

A pen of pullets, kept without a male, produced eggs at about 30 per cent less cost than an exactly similar pen with which a cockerel was kept.

Another pen, without a male, gave during the first three months about the same proportionate excess of product over an exactly similar pen with which a cockerel was kept.

In each of the two pens without male birds some pullets had begun to lay from one to two months earlier than any in the corresponding pens in which male birds were kept.

Now, friends, if this is true, think of the tremendous loss of food and loss of eggs resulting from keeping a lot of male birds running loose that are of no use to anybody. If it is not true, will somebody who is competent let us know about it as soon as possible? When you want eggs for hatching, select your best breeders and put them in a pen by themselves with your choice male birds; but do not, for the sake of humanity, if for no other reason, let your young pullets and laying hens be worried and annoyed by male birds that should have been disposed of a long while ago.

BREAKING THE WORLD'S RECORD; A PEN OF SIX HENS LAY AN AVERAGE OF 255 EGGS EACH FOR ONE YEAR.

We clip the following from the *Australian* for April 11:

Much interest has been felt in poultry circles during the past few weeks as to the probable result of the twelve-months' egg-laying competition, which came to a conclusion at the Roseworthy Agricultural College, South Australia, March 31. The two leading pens have been in immediate proximity with their output of eggs during the last week or two, and on March 29, or two days before the close of the competition, both the pens were on the same mark. After that a slight alteration occurred, and at the close of the competition the result was that Mrs. A. E. Kin-

near's pen had won with 1531 eggs for the twelve months. The pen entered by Mr. Padman laid during the same period 1528 eggs, the difference between them being only three eggs. This remarkable result broke the previous world's record, and it is quite noteworthy that the former record was established in Western Australia with 1494 eggs. Previous to the close of the competition two Victorian poultry-breeders purchased the two leading pens, Messrs. Rogen and Andrews securing the now first-prize winners, and Mrs. A. J. Duncan purchasing those that are now second. Practically there is nothing between the merits of the respective pens, and the purchasers may be congratulated on their spirited efforts to secure high-class laying strains. Both pens consist of six White Leghorn hens.

The competition was held under the auspices of the Utility Poultry Club, of South Australia, and under government supervision.

Perhaps I should have said we have hens here in America that have gone considerably higher than 255 eggs in one year; but there is no record—at least I suppose so—of a whole pen of six hens making any thing like the above. The result is of more value than one might at first think; for this woman who selected these fowls and entered them for competition had already demonstrated that each one of the six was a good layer; and as the experiment was under the supervision of the government, there certainly can be no mistake about it. Please note that not only has Australia beaten the world, but that it was done by a woman.

HIGH-PRESSURE GARDENING

By A. I. ROOT

GROWING ALFALFA AND SWEET CLOVER WITH INOCULATED SOIL.

I visited our Ohio Experiment Station a few days ago, mainly to look over their experiments with alfalfa and inoculated soil. There were several plots of alfalfa devoted to this matter of inoculating soil with nitrogen bacteria. The evidence was exceedingly plain that the inoculated soil produced a market benefit in every instance; but the pure cultures furnished by the government, and those from other sources, showed no result whatever. While there is a possibility that this latter process of introducing the nitrogen-gathering nodules may be a success, their efforts at Wooster do not show any benefit whatever. When we come, however, to bringing in soil where either alfalfa or sweet clover has been plainly showing nitrogen nodules, a very marked improvement is apparent at a glance. Prof. Williams, who has the matter in charge, informed me that some time ago he put out two little plots of alfalfa, as much alike as it was possible to make them, except that on one plot they mixed into the soil some dirt taken from the side of the road where sweet clover had been growing quite luxuriantly. He said the alfalfa was almost twice as tall where the inoculated soil was used. Prof. Green remarked in regard to this, and some other experiments with sweet clover, something like this:

"It is really astonishing that some farmers should complain about seeing sweet clover in fence-corners or along the highways when it is really one of the best friends the farmer has. It takes root, and grows in ground too poor to grow any other plant; but after it has taken ni-

trogen from the air, and made the soil fertile where it grew, it drops out of the way and lets other plants come in and grow that could not have grown on the soil had not the clover first taken root and made the soil fit for other things."

Now, in summing up, every farmer (and I might almost say every bee-keeper on the face of the earth) should grow at least a little patch of alfalfa if it can be made to grow on your soil; and the very shortest and quickest method of getting alfalfa started is to encourage sweet clover first. If you already have sweet clover, you are so much ahead. If you haven't, by all means get it started and give it a trial on the poorest and most unfertile soil you have on your place. The way some people have complained about sweet clover would almost remind us of what the good Book tells us about entertaining strangers, as we may, by so doing, entertain angels unawares.

SWEET CLOVER—SOMETHING MORE ABOUT IT.

The following is from *Hoard's Dairyman*:

What is the inclosed plant? It grows on the roadside to about three feet in height, and the roots are covered with nodules like clover. Is it of the alfalfa family? J. M. G.
Oak Grove, Md.

To the above the editor replies as follows:

The specimen inclosed appears to be the plant commonly called sweet clover. Its botanical name is *Melilotus alba*. It can not be said to belong to the alfalfa family, but it serves as a host for the same species of bacteria that the alfalfa plant requires. Soil from a locality where sweet clover grows is often used for inoculating a field for alfalfa.

The important and the principal point in the above is the last sentence. If it is true that soil taken from a locality where sweet clover grows luxuriantly can be used for inoculating a field for alfalfa, then sweet clover assumes an importance in agriculture that we have not heretofore given it credit for.

Below is something that seems to come from the same writer we quoted on p. 710, last issue. We clip it from the *Kansas Farmer*:

Many of our hills that have been worn out and washed away by having cotton planted on them for the past sixty years are now in sweet clover, and they are making money for their owners. If Mr. Grimes ever succeeds in making it a penitentiary offense to grow melilotus I am afraid we Southerners who live in the time belt will be tempted to secede again. So here is hoping the national legislators will curb the trusts but not the sweet clover.

The editor of the *Kansas Farmer* speaks in regard to the above as follows:

A few years' growth of sweet clover on gumbo land in Kansas will make first-class corn and alfalfa land of it. Alfalfa is nowhere in comparison as an improver of soil.

Since the above was dictated I have received the following from Hon. Charles E. Bessey, of the University of Lincoln, Nebraska:

Mr. A. I. Root:—I am very much obliged to you for the letter which you wrote me on May 29 in regard to sweet clover; and I am glad to know that you back me up in what I said rather mildly in my short note in the *Breeders' Gazette*. I realized that a good many men are quite "touchy" about sweet clover, and that is why I put it as mildly as I did. I think that, in a few years, we shall be able to push the matter and restore sweet clover to its proper place. I have never thought it a bad weed at all. I do not understand why people have taken such a great prejudice to it.

CHARLES E. BESSEY.
Lincoln, Neb., June 4, 1908.

It would be strange indeed if our experiment stations and professors of agriculture were making a mistake, or were not well posted in regard to the value of sweet clover.

AIR LINE RAILWAY

WE WILL SEND TO YOU FREE.

This handsomely illustrated, fifty-page,
booklet containing a most interesting de-
scription of the famous Manatee section,
being a reproduction of a series of ar-
ticles written by the editor of one of the
leading agricultural papers in the United
States after a personal investigation by
him. The articles were run in serial form
in his publication during the last four
months, and we have embodied same in
an attractive pamphlet, illustrating it with
dozens of interesting and instructive
scenes from actual life. This handsome
piece of literature will be thoroughly en-
joyed and worthy of preservation, and
will be sent free, together with pamphlet
containing a list of properties available
in the LAND OF MANATEE upon receipt of
five cents in stamps or currency to cover
cost of mailing. Our supply of this book-
let is limited, and if you want a copy you
should not delay, but write at once.

Wintering Bees in Danz. Hives

FALL RIVER, MASS., April 10, 1908.

F. Danzenbaker:—Kindly send booklet about your smoker as per your ad. in GLEANINGS, current issue, and for which I thank you in anticipation. I had ten hives, average good, last fall; now I have five that survived, and in Danzenbaker hives, and as I write they are lugging in pollen in good shape.

Yours, H. N. BRIGHTMAN,
Fall River, Mass.

(The defunct bees were in ten-frame Langstroth.)

Pretty good! five Danz. lived, five L. died.

F. DANZENBAKER, Patentee.

What's the Matter With Hilton?

WHY!

He has got his new goods fresh from The A. I. Root factory, and his 1908 catalog, and wants you to send for one free—40 pages illustrating and describing Root's goods at Root's prices. Send him a list of what goods you want, and let him tell you how much they will cost you.

Cash or supplies for beeswax at all times.

HIGHLAND FARM QUEENS

are the result of years of careful selection and judicious breeding from the best honey-gathering strains of superior long-tongue red-clover Italians in America and Italy. Highland Farm methods will produce perfectly developed, long-lived, and prolific queens. If you want bees that will winter well, build up rapidly in the spring, and roll in the honey, Highland Farm queens will produce them. We are now booking orders which will be filled in regular rotation, beginning May 15. You should get in line by placing your orders early, and avoid the rush of the busy season. Single queens, \$1.00; 6, \$5.00; 12, \$9.00. Safe delivery and satisfaction guaranteed. For further information send your address on a postal card to

HIGHLAND BEE AND POULTRY FARM, J. E. HAND, PROPRIETOR, BIRMINGHAM, ERIE CO., O.

GRAY CAUCASIAN QUEENS.

1905-1906 Queen-breeder in Apiary of Dept. of Agriculture, Washington, D. C.

During that time Caucasians were being distributed by the department so that I handled many of the imported queens and bred much of the stock which other breeders are using, and am in a position to furnish the best of Caucasian queens. They are hardy and prolific, but not great swarmers; are builders of white combs, great honey-gatherers, and their extreme gentleness has won for them the name "STINGLESS." Queens are reared from imported mother of gray type. Have three-band or leather-colored Italians also. They are hustlers.

GRAY CAUCASIANS.		PRICE LIST AFTER JULY 1.		THREE-BAND ITALIANS.	
Untested queens.....	1, \$.75; 6, \$4.25; 12, \$ 8.00.	Untested queens.....	1, \$.60; 6, \$3.35; 12, \$6.50.	Untested queens.....	1, \$.60; 6, \$3.35; 12, \$6.50.

LESLIE MARTIN, :: Birdcroft Apiaries, :: LEBANON, TENNESSEE.

ITALIAN QUEENS

And nothing but Italians. An improved superior strain is what QUIRIN-THE-QUEEN-BREEDER raises. Stock is Northern-bred and hardy—no single colony lost during the past winter; have five yards, all wintered on summer stands. Am now taking off supers of nice white-capped clover honey. Prices of bees and queens as per below:

Prices of Queens after July 1.	1	6	12
Select queens	\$.75	\$4.00	\$ 7.00
Tested queens	1.00	5.00	9.00
Select tested queens	1.50	8.00	15.00
Breeders	3.00	15.00	
Straight five-band breeders	5.00		
Two-comb nuclei, no queen	2.25	12.00	22.00
Three-comb nuclei, no queen	3.25	18.00	32.00
Full colonies on eight frames	5.00	25.00	

All queens now go by return mail. Safe arrival and pure mating guaranteed. We employ 400 to 500 swarms. Can furnish bees on L. or Danz. frames. Add price of whatever queen is wanted to nuclei or colony. No order too large, and none too small. Over 20 years a queen-breeder. Address all orders to

QUIRIN-THE-QUEEN-BREEDER, Bellevue, Ohio.

ITALIAN QUEENS

FINEST POSSIBLE BREEDING

BRED BY

F. J. WARDELL,
UHRICHSVILLE, OHIO, U. S. A.

After many years' experience as head queen-breeder for The A. I. Root Co., I am now breeding bees at the above address. My stock is equal to any now advertised, and my long experience enables me to judge very accurately the value of any strain. Mine is the celebrated red-clover stock, which has given so much satisfaction to thousands of buyers for a number of years past. If you desire something very select for breeding purposes, write to me, stating your wants, and the same will be supplied. I have no cheap or inferior queens to sell. My prices for the season are as follows:

	May to June.
Untested queen	\$1.25
Select untested queen	1.50
Tested queen	2.50
Select tested queen	3.50
Breeding queens	6.00
Select breeding queens	9.00
Extra select	1 year old, 12.00

No untested queens sent before May 15; but to secure your queens early in the season it is necessary to order now. Absolutely, all orders filled in rotation.

QUEENS of MOORE'S STRAIN OF ITALIANS

Produce workers that fill the supers, and are not inclined to swarm. They have won a world-wide reputation for honey-gathering, hardness, gentleness, etc.

Mr. W. Z. Hutchinson, editor of the *Bee-keepers' Review*, Flint, Mich., says, "As workers, I have never seen them equalled. They seem possessed of a steady, quiet determination that enables them to lay up surplus ahead of others. Easier bees to handle I have never seen."

My queens are all bred from my best long-tongued three-banded red-clover stock (no other race bred in my apiaries), and the cells are built in strong colonies well supplied with young bees.

PRICES: Untested queens, \$1.00 each; six, \$5.00; doz., \$9.00. Select untested, \$1.25 each; six, \$6.00; doz., \$11. Select tested, \$2.00. Extra select tested, \$3.00. Breeders, \$5.00 to \$10.00.

Safe arrival and satisfaction guaranteed. Descriptive circular free. Address

J. P. Moore, queen-breeder, Rt. 1, Morgan, Ky.

ITALIAN QUEENS

Bred from best stock to be had in the country, and by best methods, insuring beautiful, vigorous, long-lived queens. Prices for 1908:

	1	6	12
Untested	\$1.00	\$5.00	\$9.00
Tested	1.50	8.00	15.00
Select tested	2.00	10.00	14.00
Breeder	5.00		
Two-frame nucleus	2.25	12.00	22.00
Three-frame nucleus	2.75	15.00	28.00
Full colony on eight frames	5.00	25.00	

Add queen wanted to above.

I shall offer no Caucasians for sale this season.

E. M. GRAVES, loamosa, San Bernardino Co., Cal.

W. H. Laws

is again on hand for the coming season with a larger stock of queens than ever before.

He sold 400 queens to a New Mexico producer last May who wrote, "Your stock is far ahead of those Eastern queens I have been buying," and has placed his order for 1000 more of the Law queens to be delivered in May and June coming.

Others write that, if they had purchased all Laws queens, their crop of honey would have been doubled. Testimonials enough to fill this book. If you are going to improve your stock, had you not better investigate?

Single queen, \$1.00; dozen, \$10.00; breeders, the best, each, \$5.00. W. H. LAWS, Beeville, Bee Co., Texas.

MILLER'S SUPERIOR ITALIAN QUEENS

By RETURN MAIL; bred from best red-clover working strains in U. S. No better hustlers; gentle, and winter excellent; untested, from my SUPERIOR breeder, 1, \$1.00; 6, \$5.00; 12, \$9.00. After July 1st, 1, 75c; 6, 4.00; 12, \$7.50. Special prices on lots of 50 or more. Satisfaction and safe arrival guaranteed. Circular free. ISAAC F. MILLER, :: Reynoldsville, Pa.

5000 QUEENS

of the famous 3-banded LONG-TONGUE RED-CLOVER STRAIN OF ITALIAN BEES is what I want to sell this season.

My bees GATHER HONEY if there is any to get; ARE LITTLE inclined to swarm and sting; they please such people as The A. I. Root Co., R. F. Holtermann, W. Z. Hutchinson, Morley Pettit, etc., and if they don't please you, send in your kick.

Queens of all grades now ready.

	1	6	12
Untested queens	\$1.00	\$5.00	\$9.00
Select untested queens	1.25	6.00	11.00
Tested queens	1.50	8.00	15.00
Select tested queens	2.00	11.00	20.00
Breeders, \$5.00 to \$7.00.

One Thousand Families Wanted

for

Government-Irrigated Homesteads

Representative of the Government to Show the Land

On Tuesdays, July 21st, August 4th and 18th, September 1st and 15th, 1908, I will personally conduct land-seekers' excursions to the Big Horn Basin and Yellowstone Valley, where there is room for one thousand families on homestead lands irrigated by the Government. My services are free.

The soil is rich, the climate ideal, the water pure, and timber and coal are in abundance. The land is free, and settlers repay the Government actual cost for water—\$45.00 an acre—in ten yearly payments without interest.

Also ground-floor prices for deeded and Carey-act lands.

No cyclones, floods, or drouths.

Write for our new folder telling all about these lands. **It's free.**

D. CLEM DEAVER, General Agent
LAND-SEEKERS' INFORMATION BUREAU
 9 Q Building, Omaha, Neb.

CARTONS FOR COMB HONEY

We are prepared to furnish these cartons in several styles and in two grades of stock; also in various styles of printing. We can also execute special designs in quantities on special orders. Let us know your wants.

The Danz, open-end carton will enclose a section and pack in the regular shipping-case. We furnish it for 4x5x1½ and 1½, 3¾x5x1½, and the several widths of the 4¾ section. To hold the carton in place on the section you need a rubber band around it. These bands are not furnished with the cartons except at an extra price, and only when so ordered.

The folding carton is of a different pattern from those heretofore furnished. They tuck in at the top and bottom in a neater form, and are without tape handle. Sections packed in these cartons require shipping-cases made a little larger than the regular sizes, but such cases do not require glass. Some of our agencies have on hand some of the old-style cartons in some sizes, which may be supplied on orders unless otherwise specified. These cartons are furnished for all regular sizes of sections; namely, 4¾x4¾x1½ and 1½; also 4x5x1½. Other sizes furnished in quantities on special order.

Price List of Cartons

Danz, carton, regular size, plain or printed name blank, 50 cts. per 100; 500, \$2.25; 1000, \$4.00. Weight, 4 lbs. per 100.
 Folding cartons, regular sizes and grade, plain, 60 cts. per 100; 500, \$2.75; 1000, \$5.00.
 Folding cartons, regular sizes and extra quality, plain, 75 cts. per 100; 500, \$3.25; 1000, \$6.00.
 Extra for printing stock design, name and address blank, 50 cts. per 1000 one side; 75 cts. both sides for each color.
 For inserting name and address in design at same printing, add 50 cts. for any quantity. For printing in name and address in a stock design, after that has been printed, add 50 cts. for 100; 75 cts. for 500; \$1.00 for 1000. Such cartons can be supplied only from Medina. Special designs or printing quoted on application.

Honey-Labels

We are manufacturers of labels of almost any description. Will furnish estimates from sketches. Send for our complete catalog of forty different labels in black and colors.

The A. I. ROOT COMPANY, MEDINA, OHIO

CLASSIFIED ADVERTISEMENTS

Notices will be inserted in these classified columns at 25 cents per line. Advertisements intended for this department can not be less than two lines, and should not exceed five lines, and you must say you want your advertisement in the classified columns or we will not be responsible for errors.

Breeding queens of pure Caucasian and Carniolan races—price \$3.00. Order from A. E. Titoff, Expert in Apiculture, with Russian Department of Agriculture, Kieff, Russia. Remit with orders. Correspondence in English.

Forty Years Among the Bees

Dr. C. C. Miller

This is the plain unvarnished story of Dr. Miller's bee-keeping experiences for a term of forty years and more. He was probably the first man in America to depend solely on bees for a living, and for this reason alone the book is well worth reading. He has taken a prominent part in building up the bee industry of America in all those fateful years from the time bee culture was an infant industry until now. This has given him a fund of rich experience to draw on, and he freely uses it for the benefit of his readers. He has adopted throughout his book a simple conversational style which makes him readily understood, and renders the book easy reading to any bee-keeper. Even the beginner enjoys it. To the comb-honey producer it is of engrossing interest, for Dr. Miller is what we term a comb-honey man. In a delightful way he tells what he has done in the past, what he is doing now and what he intends to do in the future, giving the reasons for his change of mind. The extracted-honey men also like to read this simple narrative because the principles of comb-honey production are much the same as in producing extracted honey. He does not hide away the smallest detail, and one soon becomes acquainted with his family circle, his home and its surroundings, his helpers, his out-apiaries, and all that goes to make up home life and life's work. This impresses the reader in a way that the ordinary bee-keepers' manuals can not do. However, the work is not intended as an instruction-book in bee-keeping, but it affords an excellent supplement to any of our well-known manuals of bee culture. No comb-honey man should be without it, because its author is one of the most successful comb-honey men this country has produced. He has no "secrets," but tells all he knows in a way that is convincing. What adds to the interest is the fact that he lives in a locality not particularly well adapted to bees, because the winters are long and the honey flora somewhat uncertain. The print is large and clear, so that it may be read by lamp-light when the bees are in the cellar and the snow lies deep. Order a copy—only a dollar, postpaid.

THE A. I. ROOT COMPANY, MEDINA, OHIO.

Special Notices by A. I. Root

OUR CORNFIELD UP TO DATE.

I am happy to tell you that the cornfield mentioned in Homes in this issue has now, under the influence of exceedingly favorable weather and careful cultivation, the reputation of being one of the best-looking fields in this part of the State. The second planting came on nicely with favorable weather; but in order to prevent having more than four stalks in a hill, some expensive thinning-out had to be done. But I think it pays, especially at the present price of corn.

BASSWOOD-TREES—GROWING THEM FOR HONEY, LUMBER, ETC.

I would remind our readers who are interested in the matter that we have a lot of leaflets to give away, with the above title. Since this leaflet was printed in 1905, some of our basswood-trees from seedlings that came up in 1897 are now in bloom, so we can answer, at least to some extent, the question, "How long before a basswood-tree may bear honey?" These I have mentioned are furnishing quite a little bloom in ten or eleven years after the seed was planted. As the trees we send out by mail and express are from three to five years old, I think you may get some bloom from the larger size in five or six years. It will take, however, fifteen to twenty years for basswoods ordinarily to get large enough to furnish honey of any account. But as they are beautiful trees for shade, and are getting to be every year more and more valuable for lumber, I think it is an excellent plan to put them out where you want shade-trees, or where the ground is not particularly valuable for any thing else. We generally expect basswoods to be fairly in bloom by July 4, and more or less honey comes in from basswood all through July. These dates will be earlier in the South and later in the North. In Northern Michigan we get some basswood honey even in August. This year some of our early trees were opening their blossoms on the 18th and 19th of June, which is quite a little earlier than I have ever noticed them before.

A WATERING AND FEEDING DEVICE FOR LITTLE CHICKS.

A good housekeeper, as you may have noticed, keeps her things put up out of the way. When E. R. R. was a little chap his mother had so diligently instilled into his mind the importance of having his things all hung up neatly and in order that one day he almost cried, and I do not know but he *did* cry, because he could not hang up the cups and saucers; and from that day to this the Roots and Rootlets have all been instructed to hang their things up on the wall instead of letting them lie around on the floor. Even the extra shoes and overshoes must be put away out of sight. When I remonstrated, Mrs. Root explained that the work of sweeping and taking care of the room is very much less when even the shoes and overshoes are hung up on their appropriate nails; and if said shoes are to be some time out of use it is a splendid plan to put them in a light cloth bag and hang the bag up on a nail. This keeps them clean, bright, and shiny, when they are wanted in a hurry when cold weather happens to come unexpectedly.

Well, I am not writing to-day about boots and shoes, nor even about housekeeping, unless, indeed, my notes should come under the head of "Housekeeping for Poultry." If you will look on p. 638, May 15, at that little poultry-house, you will notice there is a stairway for fowls to go up into the loft. Well, under this stairway was a sitting hen; and when her chickens were hatched, to prevent the older chicks from annoying the newly hatched ones and their mother I shut them under the stairway with netting. Now, there is but little room in this small inclosure. But I wanted to provide them with both food and water, and put it in shape so it would take but little room and be protected from dirt and litter. I succeeded admirably by making two little poultry-feeders of pint tin pans after the plan shown in our book, "What to Do," page 178. These pans hang up by appropriate rings, one on each side of the doorway. Every chick has learned its location so it can get water or feed at any time when it is inclined. During the day time I let the hen out; but there is an opening at the bottom to admit small chicks, but not the older ones or the other fowls. Whenever these chicks get hungry or thirsty they go back to their well-known home under the stairway and get refreshment. These little pan feeders hang up so closely against the wall that they occupy almost no room at all. They are put high enough so the chicks can just reach the opening; and as the chicks grow, the pans can be hung to another nail a little higher up on the wall. These feeders have some advantages over any of the other devices I have seen in any of the poultry-books and journals. First, they are so close to the wall that they occupy almost no room at all; secondly, these beveled tops prevent the chicks from standing on them or from catching droppings. If put up as high as the chicks can reach, no trash or filth will even get into the openings; and after some little experimenting I am glad to note that our tinners can afford them at the low price of 15 cts. each, or two for 25 cts. If wanted by mail, the postage will be 6 cts. each extra. Of course, this price is for the smaller sizes. For full-grown fowls we want something made of a good-sized tin pan or washbasin. While the food and water are constantly in sight, none of it can get out until the chicks use it out.

I am so much pleased with this watering-device for baby chicks that I want you all to see it; and so I have decided to send one free to every one who sends \$1.00 for GLEANINGS (asking for no other premium) and includes 6 cts. for postage. I will try to give you a picture of it in our next issue.

SPECIAL NOTICES

By OUR BUSINESS MANAGER

Customers of J. W. K. Shaw & Co., Loreauville, La., will please note that, owing to an enforced absence from home, and the want of competent help, they will discontinue sending out queens for a month or two. Will report for duty later.

SWEET-CLOVER SEED.

It is still early to gather seed from sweet clover; but we desire to make the fact known early that we are in the market when this season's crop is gathered, for several tons of white-sweet-clover seed. We have already contracted for what we shall need of the yellow variety. When you have any to furnish, send us a sample, stating price you ask and quantity you can furnish.

BEESEWAX MARKET.

From this date till further notice we will pay 28 cents cash, 30 in trade, for average wax delivered here or at our branch offices. We drop the extra cent a pound we have been paying during the month of June. Be sure to mark your box so it may be identified, and write, telling how many pounds you ship, sending shipping receipt.

DANZ. SHIPPING-CASES FOR 20 4x5 $\frac{1}{2}$ SECTIONS.

We have about one hundred cases to hold 20 4x5 sections, all nailed up and packed in reshipping-cases. They have been used, but are clean and in good condition. We offer them as they stand for \$1.50 per crate of 8 cases, or the lot at \$1.25 per crate. This is a special bargain, as they are all ready to pack honey in for shipment at less than the price of new cases in the flat.

SECOND-HAND 60-LB. CANS.

We have on hand from one to two hundred second-hand five-gallon cans, two in a case, in fair condition, which we offer at \$4.00 for 10 cases; 25 cases or over, at 35 cents. They are all looked over, boxes put in good shape, and no cans included which are rusted on the inside so far as we can determine by careful examination. They ought to be worth this price, especially for cheap grades of honey.

JAPANESE BUCKWHEAT FOR SEED.

The demand for this has been so brisk that we have disposed of our stock of nearly 200 bushels, and will doubtless receive further orders which we shall not be able to fill if we do not succeed in finding a further supply. If any of our readers have any surplus seed, or know of any for sale, we should be pleased to hear from you with sample, stating quantity you have to furnish, and the price, 50 lbs. to the bushel.

NO. 2 OR B GRADE SECTIONS.

We have plenty of this grade in all regular styles and sizes except 4 $\frac{1}{2}$ x4 $\frac{1}{2}$ x1 $\frac{1}{2}$ 2 beeway. We have over a million of this size in stock in A grade, and are out of B grade. If you want this size promptly, do not order B grade. The lumber we are working now is so nice that it does not produce very many B-grade sections. For several weeks we have been working off colored lumber to produce a larger proportion of B grade; but this is all used up, and we are now using new stock cut the past winter, which is very nice and white.

FIRE AT ST. PAUL BRANCH.

Since our last I have visited our St. Paul branch to adjust the fire loss with the insurance company. The damage to building and goods amounted to about \$2500, fully insured. In separate warehouses there was over \$2600 worth of goods untouched. Many of those in the building where the fire occurred escaped injury, while others were only slightly damaged by smoke and others by water. Some goods were, of course, destroyed. On another page we list some of the slightly damaged goods at special prices. There are others which were not listed in time for this issue. Those, especially in the Northwest, who are interested will do well to communicate with our St. Paul office. There are some rare bargains in the lot. The price was put low to close them out quick and make room for new stock. They are supplied with every thing needed in fresh goods, having received a car before this paper is mailed, added to the good stock already on hand.

JAMESTOWN, N. Y.

FIRE SALE

... of ...

BEE-SUPPLIES

AT
ST. PAUL
MINN.

Of special importance to North-western Bee-keepers.

Owing to a fire in our St. Paul warehouse we are obliged to sacrifice a considerable portion of our stock which suffered from smoke and water. In most cases the goods are not materially injured, yet at the same time they can not be sold for new goods. In some instances the goods are slightly scorched, but not enough to hurt. We have put the prices down low enough so that the purchaser will find he has saved considerable money by the transaction.

**PARTIAL
LIST OF
DAMAGED
GOODS.**

The injured goods are not all listed here. Better go and inspect the stock— You can secure a bargain.

Address only

A. I. ROOT CO., H. G. ACKLIN, Mgr.

H. G. ACKLIN, Mgr.

1024 Mississippi St.

ST. PAUL, MINN.

WOULD YOU HAVE RAISED YOUR HAND?

"All those who want to go to heaven, please raise their hands," said the Sunday-school teacher to a class of little boys.

One boy's hand did not come up.

"Why, James, don't you want to go to heaven?"

"No, ma'm; I prefer to stay on earth."

Most of us would agree with James, just for the present. And, after all, old Earth is a pretty good paradise if we are of a mind to make it so or know how to get at its beauties, instructions, entertainments, and interests. The Maker pronounced it "good," but many of us fail to get at the large fullness of its goodness.

The poet Browning said, "God must be glad one loves his world so much."

I have often wished Browning had told us also what God thinks of those who do not appreciate his beautiful world.

By the way, in which class are you? If you really desire to know more and love better this wonderful and beautiful world, you will find efficient, inspiring aid in

THE GUIDE TO NATURE.

This magazine is in the spirit of James, who thought this earth is a pretty good place for residence—just for a while. Even if you are ninety years of age you may keep young in spirit, and retain the charm of original relation to natural objects.

Let us tell you how to do it. I mean you who deeply love honey-bees and have a big heart for landscapes and plant and animal life—you who find education and recreation in natural objects—you who ward off laziness or discouragement by saying with the Psalmist, "I will lift up mine eyes unto the hills, from whence cometh my help."

Let me tell you the rest of the story.

EDWARD F. BICELOW, the nature-study bee-man.

Honey Markets.

The prices listed below are intended to represent, as nearly as possible, the average market prices at which honey and beeswax are selling at the time of the report in the city mentioned. Unless otherwise stated, this is the price at which sales are being made by commission merchants or by producers direct to the retail merchant. When sales are made by commission merchants, the usual commission (from five to ten per cent), cartage, and freight will be deducted, and in addition there is often a charge for storage by the commission merchant. When sales are made by the producer direct to the retailer, commission and storage, and other charges, are eliminated. Sales made to wholesale houses are usually about ten per cent less than those to retail merchants.

EASTERN GRADING-RULES FOR COMB HONEY.

FANCY.—All sections well filled, combs straight, firmly attached to all four sides, the combs unsoiled by travel-stain or otherwise; all the cells sealed except an occasional one, the outside surface of the wood well scraped of propolis.

A No. 1.—All sections well filled except the row of cells next to the wood; combs straight; one-eighth part of comb surface soiled, or the entire surface slightly soiled; the outside surface of the wood well scraped of propolis.

No. 1.—All sections well filled except the row of cells next to the wood; combs comparatively even; one-eighth part of comb surface soiled, or the entire surface slightly soiled.

No. 2.—Three-fourths of the total surface must be filled and sealed.

No. 3.—Must weigh at least half as much as a full-weight section.

In addition to this the honey is to be classified according to color, using the terms white, amber, and dark; that is, there will be "Fancy White," "No. 1 Dark," etc.

NEW COMB-HONEY GRADING-RULES ADOPTED BY THE COLORADO STATE BEE-KEEPERS' ASSOCIATION.

No. 1 WHITE.—Sections to be well filled and evenly capped except the outside row, next to the wood; honey white or slightly amber, comb and cappings white, and not projecting beyond the wood; wood to be well cleaned; cases of separated honey to average 21 pounds net per case of 24 sections, no section in this grade to weigh less than 13½ ounces.

Cases of half-separated honey to average not less than 22 pounds net per case of 24 sections.

Cases of unseparated honey to average not less than 23 pounds net per case of 24 sections.

No. 1 LIGHT AMBER.—Sections to be well filled and evenly capped, except the outside row, next to the wood; honey white or light amber; comb and cappings from white to off color, but not dark; comb not projecting beyond the wood; wood to be well cleaned.

Cases of separated honey to average 21 pounds net per case of 24 sections; no section in this grade to weigh less than 13½ ounces.

Cases of half-separated honey to average not less than 22 pounds net per case of 24 sections.

Cases of unseparated honey to average not less than 23 pounds net per case of 24 sections.

No. 2.—This includes all white honey, and amber honey not included in the above grades; sections to be fairly well filled and capped, no more than 25 uncapped cells, exclusive of outside row, permitted in this grade; wood to be well cleaned, no section in this grade to weigh less than 12 ounces.

Cases of separated honey to average not less than 19 pounds net.

Cases of half-separated honey to average not less than 20 lbs. net per case of 24 sections.

Cases of unseparated honey to average not less than 21 lbs. net per case of 24 sections.

CINCINNATI.—The market on comb honey is very slow; some new goods have arrived, but there is no demand, and it is selling slow at 14. There is some new white-clover extracted honey coming in, selling at 7½. Amber in barrels is selling at 6 and 6½. Beeswax is selling at \$33.00 per 100 lbs.

July 1.

C. H. W. WEBER, Cincinnati, O.

ST. LOUIS.—The honey market is very quiet. There is absolutely no demand for comb honey. Extracted honey is also neglected, consequently the prices have declined. Quote as follows: Fancy white comb honey, 15 to 16; No. 1, white and amber, 12 to 14; broken and defective, less. Extracted white, in cans, nominal at 8 to 8½; amber, 7 to 7½; in barrels, 5½ to 6; granulated extracted honey sells at less. Beeswax, 29 for prime; impure and inferior, less. R. HARTMANN PRODUCE CO.,

July 1

St. Louis, Mo.

NEW YORK.—Comb honey: The demand is next to nothing, and has been so for the past four months. A few crates of fancy No. 1 white are called for once in a while, while off grades and dark are entirely neglected. As there is practically no demand, quotations are simply nominal. We have more in stock than we can dispose of. The honey will have to be carried over until next fall. We can not encourage shipments of comb honey, as we do not think we shall be in position to render account of sales within reasonable time. Extracted honey: Demand better and market slightly improving. -New crop is arriving quite freely from the South, where the yield seems to have been pretty large. We quote California white sage at 8½ to 9; light amber, 7½ to 8; amber, 6 to 6½; new crop Southern from 58 to 75 per gallon, according to quality. West India honey is arriving in fairly good-size lots and finds ready sale at from 60 to 62 per gallon, duty paid. Beeswax in good demand, and firm at 30 to 31.

June 24.

HILDRETH & SEGELKEN,
265-7 Greenwich St., New York.

ZANESVILLE.—There is a little better demand for honey on this market. No. 1 to fancy white comb brings wholesale about 17 cts. for Cuban and 18 for native. For clover honey grading No. 1 to fancy, jobbers are paying 15 cts. on arrival. There is a very limited demand for extracted. For good yellow beeswax I offer 30 cts. f. o. b. here in exchange for bee-supplies.

EDMUND W. PEIRCE,
Zanesville, O.

July 7.

INDIANAPOLIS.—A large crop of honey has been secured throughout the clover belt, and the quality is above the average. The demand is excellent, but thus far no established schedule of prices can be named. I would urge producers who ship their honey to have an understanding about prices, and not consign their goods to commission houses, as it is the commission house that beats down the prices in competition. Beeswax brings 28 cts. cash or 30 in exchange for goods.

Indianapolis, July 4.

WALTER S. POWDER.

DENVER.—We are entirely closed out of comb honey, and ready to receive consignments of new-crop comb, the first arrivals of which should move quickly at good prices if fancy stock. Extracted honey is in fair demand. We quote white extracted, 8 to 9; light amber and strained, 6½ to 7½. We pay 25 for clean yellow wax delivered here.

THE COLORADO HONEY-PRODUCERS' ASS'N,
Denver, June 23. F. Rauchliss, Manager.

SAN FRANCISCO.—The receipts of honey are still quite light, and every one is preparing for a short crop. Prices remain unchanged but firm. All honey is sold readily on arrival. Water-white comb, 16 to 17; white, 15; water-white, extracted, 8 to 8½; light amber, 7 to 7½; dark amber, 5½ to 5¾; candied, 5½ to 5¾. —*Pacific Rural Press.*

LIVERPOOL.—Our market is firm, though no business has been done. Only a little inquiry, and quotations remain unchanged. Chilean, 4 to 6½; Peruvian, 3½ to 5½; California, 7½ to 9; Jamaican, 4 to 5½; Haiti, 6½ to 6¾. Beeswax is firm. African, 30 to 32; American, 31 to 34; West Indian, 29 to 32; Chilean, 31 to 36; Jamaican, 34 to 35.

TAYLOR & CO., 7 Tithebarn St.

CINCINNATI.—The demand for comb honey has fallen off considerably in the past twelve months. Last year the comb-honey market was bare in February, but this season finds an abundance of that article everywhere at this date, which is late for last season's crop. We can not tell at present what effect this state of affairs will have upon the market when the new honey comes in. The market on extracted honey shows some life, but is not moving rapidly. Quote amber in barrels at 6 to 6½, according to the quality; fancy extracted honey, 7½ to 9. For choice yellow beeswax, free from dirt, we are now paying 28 cts. cash and 30 in trade, delivered here.

June 25.

THE FRED W. MUTH CO., Cincinnati, O.

PHILADELPHIA.—The prospects at present are for one of the largest crops of honey we have seen in the East for the last ten years. The result is, prices are uneasy and have a strong downward tendency. Some few little lots of comb honey are being offered, but not enough to establish a price. We are looking for very low prices the coming season. Beeswax is firm at 28.

June 30.

W. M. A. SELSER, Philadelphia, Pa.

BOSTON.—Fancy white comb honey, 17; No. 1 white comb, 16; California white sage, extracted, 9; California light amber, 8; Southern honey in barrels, slow sale, 5 to 6.

June 22.

BLAKE-LEE CO., Boston, Mass.

THE DANZENBAKER SMOKER

PAT. OCT. 3, '06, JUNE 4, '07

GOLD MEDALS

St. Louis Exposition, 1904
Jamestown Exposition, 1907

**IS THE BEST,
STRONGEST,
COOLEST,
CLEANEST,
CHEAPEST,
AND LARGEST
SMOKER SOLD
FOR A DOLLAR**

The perforated side grate seen above holds a removable, metal, asbestos-backed fire shell, preventing burning the tin off the outer case, and deflects the air at right angles, preventing back draft to the valveless bellows. The air, passing to the back and over the top, cools and expels the smoke, fanning the burning fuel at top or side till all consumed, giving cool smoke for hours from one filling. It can't clog. No top-heavy cap to choke with soot; no valve to fail; no holes shedding sparks or hot ashes.

Four years' sales prove its success beyond a doubt, expensive dies making it uniformly perfect as possible to devise. We confidently guarantee full satisfaction or refund the price.

Price, \$1.00; 3 for \$2.50; by mail, add 25c. each

Send address of yourself and Bee friends for 8-page leaflet on "Smoker," and facts about Bees and Queens, 80 pages, free.

F. DANZENBAKER Norfolk, Va.
or Medina, O.

Mr. T. S. Hall, Jasper, Ga., breeder of fine Italian queens, writes, June 11, 1908: "The three smokers came all O. K., and they are dandies, sure; are good smokers. We burn corn-cobs in them all right. We may send you orders for smokers, as several have expressed a desire for one."

Dr. R. Munson, Washington, D. C., says: "Your new smoker has a much stronger blast than the first one. I have been using the first one with a roll of newspaper, first starting the fire at the bottom, and it works finely that way, and stays lit all day. Firing it up at 8 A. M. and using it half an hour in my queen-rearing hives, and, setting it aside, I usually find it still smoking ready for use at 4 or 5 P. M."

SACKETT WRAPPERS

(Transparent) FOR COMB HONEY

NOW BEING USED BY LARGE PRODUCERS

SUBURBAN LIFE.

The above is a periodical that has sprung into a wide popularity the last few years. There are several reasons for its large circulation. One is the whole-souled enthusiastic way it praises rural life. This causes the city man to remember the days of his youth when he was a raw-looking country boy picking blackberries on the old homestead. It causes the rural dweller to take a new interest in his quiet existence. He spruces up. His home is made far tidier and homelike than it used to be, because he is emulated by the excellent example of others whose work he finds exemplified in *Suburban Life*. The beautiful pictures he sees in this magazine fill him with a heart-felt desire to have a little of heaven here on earth. If the Goodman of the house does not appreciate the charm of these pictures his wife does to the very utmost; and if he does not subscribe, she will. Many who never half appreciated the beauty of the fields and woods around the old homestead have been brought to a realizing sense of the charm of nature right where they live. They realize that country life is not lonely with lovely plants, birds, animals, and insects all around them in great numbers. The bright ideas they get from such magazines have a real value in dollars and cents, to say nothing about the inspiration conveyed by very many beautiful pictures, so that the subscription money is not begrudged. *Suburban Life* works on a far higher plane than the ordinary farm paper, and yet it does it in such a manner that he who runs may read, for the language is direct and simple. Many suppose that magazines of this class are gotten up for city folks or fancy farmers with much money to spend; but as a matter of fact they are not. The idea is to glorify rural life, to the end that the dwellers will be happier and more contented with their lot because of the great possibilities all around them.

A GOOD SEASON FOR QUEENS.

The season has proven thus far to be an exceptionally good one for raising queens. Every thing has been in the queen-breeders' favor, so that they not only have plenty of them but the quality is exceptionally high. We wish, therefore, to suggest that this is a very favorable time to purchase queens—that is, just as soon as the supers are off and every thing cleared up. By putting young vigorous queens at the head of every colony, you provide a sort of insurance for next season. There will be less trouble in wintering and springing, and also less swarming. The queen-breeders who are using our columns are a very intelligent class of men, and we believe they are doing their best to give buyers a square deal.

WEST MICHIGAN STATE FAIR, GRAND RAPIDS, SEPT. 14—18, 1908.

PREMIUM LIST OF THE APIARIAN DEPARTMENT.

A. G. Woodman, Supt., Grand Rapids.

Competition open to Michigan only.

1. Entries must be made before 6 P.M., Sept. 3, 1908.
2. Nuclei must be exhibited in such shape as to be seen on at least two sides, and should not be so crowded with bees but that the queen can be easily found.
3. Bees must not be allowed to fly during the hours of exhibition; all honey shown to be the product of the exhibitor, and produced during the season of 1908.
4. All strains of bees are to be bred by the exhibitor, and grown or produced in Michigan. They must be plainly labeled, and placed in observatory hives, the appearance of the hive to be considered.
5. In judging the display of comb and extracted honey, a quantity up to the amount of 500 lbs. each will be considered in making the awards.
6. Exhibits of all kinds of implements and bee-keepers' supplies are invited, for which space will be provided. A diploma will be awarded for the best exhibits.
7. In judging honey, etc., the following scale of points will be used: Style, 10; body, 20; color, 30; flavor, 40.

LIST OF PREMIUMS.

- 1203 Display of comb honey—quality, quantity (up to the amount of 500 lbs.); appearance and condition for market to be considered. Premiums will be paid on a basis of 5 cts. per section for first; 4 cts. per section for second, and 3 cts. per section for third, for actual number of sections of comb honey shown. Maximum amount of premiums, \$25.00, \$20.00, \$15.00 respectively.
- 1204 Specimen case of comb honey, not less than 10 lbs., quality and condition for market to be considered—\$5.00, \$3.00, \$2.00.
- 1205 Display of extracted honey—quality, quantity (up to 500 lbs.); appearance and condition for market to be considered. Premiums to be paid on a basis of 5 cts. per lb. for first; 4 cts. per lb. for second, and 3 cts. per lb. for third, for actual

amount shown. Maximum amount of premiums, \$25.00, \$20.00, \$15.00 respectively.

1206 Specimen of extracted honey, not less than 1 lb.—flavor, color, body, and style to be considered—\$3.00, \$2.00, \$1.00.

1207 Display of extracted honey in granulated form—appearance, quality, and quantity (up to the amount of 150 lbs.) to be considered. Premiums are to be paid on a basis of 5 cts. per lb. for first; 4 cts. per lb. for second, and 3 cts. per lb. for third, for actual number of pounds shown. Maximum amount of premiums, \$7.50, \$6.00, \$4.50 respectively.

1208 Most attractive display of beeswax—quality and quantity (up to the amount of 150 lbs.) to be considered. Premiums are to be paid on a basis of 5 cts. per lb. for first; 4 cts. per lb. for second, and 3 cts. per lb. for third, for actual number of pounds shown. Maximum amount of premiums, \$7.50, \$6.00, \$4.50 respectively.

1209 Most attractive display of best honey-producing plants, pressed, mounted, and named, not to exceed 25 varieties—\$5.00, \$3.00, \$2.00.

1210 Italian bees and queen, single-frame nucleus, in observatory hive—\$3.00, \$2.00, \$1.00.

1211 Black bees and queen, single-frame nucleus, in observatory hive—\$3.00, \$2.00, \$1.00.

1212 Carniolan bees and queen, single-frame nucleus, in observatory hive—\$3.00, \$2.00, \$1.00.

1213 Caucasian bees and queens, single-comb nucleus, in observatory hive—\$3.00, \$2.00, \$1.00.

1214 Queen-rearing nucleus showing frame of queen-cells, in observatory hive—\$5.00, \$3.00, \$2.00.

1215 Full colony in full-size observatory hive, showing different parts and appliances of hive, most instructive—\$3.00, \$2.00, \$1.00.

1216 Largest, best, and most instructive display of nuclei of different races of bees in single-comb observatory hive—\$5.00, \$3.00, \$2.00.

1217 Largest, best, most interesting, attractive, and instructive exhibition in this department, all things to be considered—\$15.00, \$10.00, \$5.00.

RASPBERRY HONEY

My brother and myself have five apiaries in the wild-red-raspberry region of Northern Michigan, where we are harvesting a crop of unusually fine quality. Not a pound is extracted until it has been thoroughly ripened and sealed over, and it is thick, rich, and delicious. We are putting it up in bright new 60-lb. tin cans, two in a case (the ends of the cases are bound with hoop iron to protect them in shipment), and offering it at ten cents a pound—\$12 00 for a case of two cans. To some this may seem a trifle high in price; but it must be remembered that it costs more to produce such honey as this, and it is worth more;

besides, to a certain extent it is a novelty. It is *raspberry* honey—a honey with a flavor all its own—a flavor that smacks of the wild red raspberry of the woods. It is the honey that won the gold medal at the Jamestown Exposition against all other honeys from all over the United States. The dealer who builds up a trade for this honey can hold it against all odds.

If not acquainted with this honey, send me ten cents and I'll mail you a generous sample, and the ten cents may apply on the first order that you send.

W. Z. HUTCHINSON, Flint, Mich.

LISTEN!

DO YOU HEAR THOSE BEES WORKING?

Soon they will want room or will swarm.

Have you gotten your hives and supplies? If not, send your order at once. If you have The A. I. Root Co.'s catalog you can order from it. We sell their goods at their factory prices. We can fill your orders promptly now. Write for further information and our 40-page catalog.

JOHN NEBEL & SON SUPPLY CO., HIGH HILL, MONTG. CO., MISSOURI.

BEE KEEPING

will be a profitable industry this season.

Honey is high—short crop last year. The shortage of the honey crop for 1907 in the United States warrants bee-keepers to increase their colonies. About a half crop was produced, and in California, where the cheap honey comes from, only a quarter of the average crop was produced.

Get Ready Now for More Honey

Let us send you our catalog. We are manufacturers and sell only our own make of bee-supplies. Minneapolis is the largest lumber-distributing point; the Mississippi river furnishes us power, and our organization and labor conditions are the best for economical production. Send us an estimate of your requirements and let us give you prices. We have a large stock of standard bee-supplies on hand.

The A. I. ROOT COMPANY
SYRACUSE, NEW YORK

TO THE BEE-KEEPERS of CANADA.

WE are pleased to say that we are able to offer, in Canada, goods manufactured by The A. I. Root Co. While we do not offer every thing listed in their catalog, we have selected such articles as we believe will best meet the wants of the Canadian bee-keepers.

The heavy duty and freight charges we have to pay make it impossible for us to sell in Canada at Root's prices. We have, however, made prices as low as possible, and in no case do we charge nearly as much extra as the amount of freight and duty we ourselves have to pay on the goods.

We would ask you, when comparing our prices with those of other dealers, to take into consideration the QUALITY. If you do so we feel satisfied that you will place your order with us. The splendid quality of the material sent out by The A. I. Root Co. has given "Root's Goods" a world-wide reputation. Remember, "The best is cheapest."

READ WHAT EXPERTS SAY OF IT

The Christmas mail brought me what is probably as useful and beautiful a Christmas present as I ever received—a morocco-bound copy of the new edition of the ABC and XYZ of Bee Culture. Bee books and journals have come to my desk of which it seemed as though the least said the better. Not so with this book. On the contrary, it seems as though words were lacking to do it justice. There are many other bee-books, each filling its niche, but, in all the world, there is nothing so comprehensive as the ABC and XYZ of Bee Culture. There is no point in the wide domain of apiculture that is not touched upon in this volume, and the information is the very latest and most authentic, well written and well illustrated. The amateur and the expert are both served equally well.—W. Z. HUTCHINSON, editor and proprietor of the *Bee-Keepers' Review*, and author of *Advanced Bee Culture*.

No bee-keeper's library can be at all complete without a copy of this magnificent apian work. It has reached a sale of over 100,000 copies already, being the most largely sold book on bees in the world. Better send to us for a copy to read during the long winter evenings.—*American Bee Journal*.

This work of 536 pages is, as its name implies, a complete cyclopedia of everything pertaining to bees and bee-keeping. It was originally compiled by A. I. Root, who in the 1877 preface, after stating his indebtedness to Langstroth, Quinby, and others, says that "A great part of this ABC book is really the work of the people, and the task that devolves on me is to collect, condense, verify, and utilize what has been scattered through thousands of letters for years past." Since the first copy of this work appeared, now thirty-one years ago, it has undergone many revisions, and has had many additions, both of letterpress and illustrations, while the rapid advancement in bee culture has made it necessary in many cases to remove whole articles and rewrite them entirely. The revision has been ably carried out by E. R. Root, the present editor of GLEANINGS, who has had the assistance of a number of well-known and able men. In the preface the names of the writers of the different articles are given. For instance, we find Dr. C. C. Miller writes on honey-comb and out-apiaries; Dr. E. F. Phillips on the eye, parthenogenesis, and scent of bees; E. R. and H. H. Root on wax and wintering, both of these having carried out a number of experiments on these subjects. There are also articles by W. K. Morrison and Mrs. Comstock. It seems almost superfluous to say any thing about a book of which already 100,000 copies have been sold; the simple fact speaks for itself that it fills a want, and is an attestation of its worth. Among the articles that have been revised we find the new methods of queen-rearing described, so that the practical bee-keeper will have the latest and best ideas on the subject before him for reference. The new methods of wax-production are treated in an exhaustive manner; and as this subject is of more importance than formerly, greater space has been devoted to it. We have nothing but good words for this work, and recommend our readers to get a copy of the 1908 edition. The work is profusely illustrated and beautifully printed, and is a credit to the publishers.—By T. W. COWAN, Esq., editor of the *British Bee Journal*. Mr. Cowan is the author of two first-class books on bees and bee-keeping, "The Bee-keeper's Guide" and "The Honey-bee."

"If goods are wanted quick, send to Pouder."

FLOWING WITH MILK AND HONEY

By the Bee Crank.

The official forecast for the year 1908, from all sections of the country, remind one of the figurative language of the Israelites who were sent to spy out the land of Canaan—it is a land flowing with milk and honey. Not in many years has there been the promise of such an abundant crop, and the bee-men are coming in for their share of the good things. There will be plenty of honey of a very high grade.

How will you profit by it, Mr. Beeman? Most surely by securing the supplies needed to enable you to harvest and to handle the yield that is yours for the taking, and by securing these supplies where you can get them promptly.

I can help you. There are no delays at the critical moment when

you order standard goods from me. The goods are here waiting for you, and they go forward the day your order reaches me. My specialty of prompt shipments brings me many orders from far and near. If you have never ordered from here, put me to the test with a trial order.

I have a full supply of all seasonable goods; shipping-cases, honey-jars, sections, the latest in hives and honey-extractors. I should like to send you my illustrated catalog, which explains the details.

Hoosier-Italian queen by return mail. Select untested, \$1.00; untested, 75 cts.

I pay 28 cts. cash or 30 cts. in trade for good average beeswax, and shall be glad if you will favor me by sending your wax here.

Walter S. Pouder,
513-515 Massachusetts Avenue, Indianapolis, Ind.

JULY 15, 1908

NO. 14

STRAY STRAWS

DR. C. C. MILLER

WHITE CLOVER showed its first blossom May 25; yellow sweet clover, June 1; white sweet clover, June 24. That 23 days of yellow in advance of white sweet clover would be quite an item in a year of failure of white clover.

A FRAME of young brood helps to decide whether a virgin is present in a nucleus. If no cells are started it is reasonably certain that she is there all right. But two or three cells are sometimes started, even with a virgin present. If a whole lot are started you may count your virgin is gone. [Right you are, on both propositions.—Ed.]

M. M. BALDRIDGE, instead of putting a weak colony over a strong one in spring, reverses the Alexander plan, putting the strong colony over the weak one on the stand of the strong one, an excluder between. This, when dandelions or other flow is on, at sundown, not smoking the weak colony, and smoking the strong one just enough to make the bees leave the bottom-board. Three years' trial of both plans has shown that the weak colony builds up more rapidly by the Baldrige plan.

WHETHER because of the yellow bees I have been getting in, or because of the season, swarming is very bad this year. One colony that swarmed, not only had no advanced cells but not even an egg could be found in a queen-cell in the hive! [By "yellow bees" we suppose you mean Italians. Do we infer that the latter swarm more than your hybrids and blacks? If all of them swarm, then we should attribute this swarming to the peculiarity of the season rather than to the yellow blood.—Ed.]

J. E. HAND, referring to your remarks, p. 819, I will say that I know of no reason for thinking that my colonies that stored under the brood-nest were in an abnormal condition. The large number of colonies engaged in it rather precludes the idea of played-out queens; and, although I can not say positively, my impression is that among the number were some that made the very best records at storing. I think, friend Hand, if you could have seen the white combs of honey built in those spaces in bottom-boards, with the vigorous colonies above, you would have shaken your head and said, "Well, every now and then we must give up some of our preconceived notions; there goes another."

I DON'T KNOW why Hervey B. Jones should have had his failure with foundation splints. You are right, Mr. Editor, that splinted foundation should be given only when honey is coming

in; but even if given in a dearth I've never known the bees to do much at cutting out the splints. The trouble is that, in a dearth, they dig away a passage between foundation and bottom-bar. The only thing I can think of is that the splints were not properly coated with wax. They should be boiled in wax till all the moisture fries out, and, when taken from the wax to be fastened on the foundation, the wax should be merely hot enough to be liquid, but not hot enough to run entirely off the splints. With the splint well coated with wax, why should the bees tear at it any more than at the foundation itself?

WHITE CLOVER is more abundant than ever before. I think I've said that before. It was true then; it's more emphatically true now. Fields are far and away whiter with the bloom than ever before. There's nectar in it too. Not only do the bees drop at the entrance as they come in heavily laden, but they drop on the hives and surrounding grass. I suspect there is five times as much nectar as the bees can take care of. [This is the kind of report that we are getting from many sections of the clover belt. It is very remarkable the way reports have come in. One locality will show a most tremendous honey-flow, while another one, only a few miles away, and in the same State, will show "almost nothing doing." It is peculiar this year that large areas will produce a large amount of honey; but in those areas there are pockets where there is little or no nectar.—Ed.]

I THINK I've heard it said that, under some conditions, as much comb as extracted honey can be produced. I don't see how that can be if the bees have no comb to build for the extracted. Say that it takes a pound of comb to contain 20 lbs. of honey, or 5 lbs. of comb for 100 lbs. of honey. If it takes 10 lbs. of honey to make one of wax it takes 50 of honey to make that 5 lbs. of wax. So 150 lbs. of honey must be gathered for 100 lbs. of comb honey. If these figures be correct, there can in no case be less than 50 per cent more extracted than comb. To be sure, it may take less than 10 lbs. of honey to make a pound of wax; but even if it takes only 5 lbs. of honey for one of wax, that still makes 25 per cent more of extracted than comb. Then it must not be forgotten that it takes bees to secrete the wax and to build the comb. If bees are released from this duty in the extracting-super it means a greater number of bees in the field. Don't tell me that bees won't go afield before 16 days old. I've seen them do it under stress when only 5 days old, and I don't believe a bee will loaf around doing nothing until 16 days old if there is no housework for her to do, and she can find work in the field. [We should like to see this question discussed by those who are in position to give us

some data and facts, as it has a very direct bearing on the question of whether one should produce comb or extracted honey.—ED.]

WALTZING bees, are they carrying on that way to shake off wax scales or to show they've found some new honey or pollen? p. 830. If it were throwing off wax scales, there would be a lot of them at it all the time when wax is being secreted, and generally it's only a single bee at a time. I'm skeptical about the heralding a new find of honey or pollen. If Prof. Gaston Bonnier is correct about the explorers who make the finds, waltzing should be seen only in the morning. Is it thus limited? Besides, explorers are supposed to have attained considerable maturity; and did you ever see any but a rather youthful bee engaged in the dizzy waltz? There's one good reason I can see for it: Whenever a man thinks he knows all about bees, you can settle him by asking, "What is the meaning of bees waltzing and raking?" [The one who thinks he "knows it all" will often answer your last question with a degree of assurance that makes one feel like putting him down as an ignoramus. However this may be, it is generally believed that the waltzers are young bees, and that their act is a sign of joy that they have found pollen, and that they take this means to communicate the knowledge to their fellows.—ED.]

"FIGURES printed on heavy tagboard manila, boiled in paraffine," are commended, p. 799, for hive-numbering. A few years ago I got a set of 100, and within two years I had to replace them with a hand-painted set. They don't fill the bill at all. I think, Mr. Editor, there are thousands of bee-keepers who would not object to $\frac{3}{4}$ cent for each aluminum figure. That would make it cost \$1.44 to number the first 100 hives (a great many would need no more), and \$2.25 for each succeeding 100. For one, I'm ready to put in an order for a set with duty added to the price. But can't they be made as cheaply here as in Germany? [When you say you have tried figures printed on heavy cardboard manila boiled in paraffine we suspect you refer to number-tags we sent you two or three years ago. Those were soaked in *linseed oil*, not boiled in *paraffine*, as you apparently infer. One who says he has tried both the paraffine boiled, and the tag soaked in linseed, says there is a very great difference between the two. The former will hold its color and shape, while the latter will turn black as you describe.]

No, we can not make the metal tags as cheap as they can be made in Germany. Labor is cheaper there, especially skilled labor, and that is what is required to make dies. If the bee-keepers of this country will put up a strong enough demand we will see that that demand is supplied.—ED.]

THE Corn Products Co., according to newspaper reports, have placed an order in Argentina for 100,000 bushels of corn to keep their factories running. They claim to be losing money at present prices, and that is probably true. They require corn at low prices. Hitherto they have made much of the fact that they were heavy buyers of American corn. Continued high prices would force them out of business.

W. K. M.

EDITORIAL

By E. R. ROOT.

HONEY will be of exceptionally fine quality this season, for it will be mainly clover. If it is clover, it is good enough for anybody.

ARE you going to the National convention that is to be held in Detroit Oct. 13, 14, and 15? This convention promises to be very interesting as well as a big one. Don't miss the chance to attend.

WHITE clover is still hanging on in our locality; and, what is more, reports from a large number of localities, north and south of the Ohio River, and as far east as the Atlantic coast, show the same thing. Strangely enough, there are pockets where there is drouth and no honey, surrounded by moisture and honey.

GEO. E. HILTON WINS A MEDAL AT JAMESTOWN.

AT the Jamestown exposition there were not many honey exhibits. The one made by Ohio called forth considerable comment. But there was one exhibit by Mr. Geo. E. Hilton, President of the National Bee-keepers' Association, that won the gold medal. Unlike some of these so-called medals it was of solid gold, with an intrinsic value of \$175.

A HIVE-CAGE.

A SPLENDID thing to stop robbing and to catch swarms is a little wire cage, just large enough to be set down over the largest hive, and leave six or eight inches clearance around the hive and on top. If one discovers a swarm just coming out, he can clap this right over the hive and catch nearly the entire swarm. The whole cage may then be picked up and the bees dumped in front of the hive that has been prepared for it. During the robbing season such a cage is invaluable.

BEE-KEEPERS, ATTENTION!

THE following has just been received:

The most dreaded of all diseases, foul brood, exists in various parts of Massachusetts. This disease can be easily eradicated. It is of great importance that all bee-keepers satisfy themselves at once whether they have the disease. To enable them to determine this point, and in order to teach them how to get rid of the disease, the State Board of Agriculture and the Massachusetts Experiment Station will unite in holding an institute to demonstrate the treatment necessary to cure it.

Mr. Charles Stewart, one of the foul-brood inspectors of New York, has been engaged to make a demonstration. This will take place in Ludlow, at the farm of Mr. E. N. Fisher, on July 21. Mr. Stewart will show the proper methods of treatment, and no bee-keeper in the State should fail to be present at the demonstration.

WM. P. BROOKS, Director.

GREASY WASTE AS A SMOKER FUEL.

WE have several times spoken of the excellence of greasy waste, such as can be obtained at a machine-shop or printing-office, as a smoker fuel. It gives a pure lasting smoke with almost no sparks; and, what is more, it does not gum up the smoker as does ordinary fuel. In our opinion, it leaves every thing else clear in the shade. The waste should not be too greasy, but just such as an ordinary machine-shop is glad to get rid of for the asking. Two or three bushels of it will

last one almost an entire season, as it goes a long way.

VERY LITTLE HONEY IN SOUTHERN CALIFORNIA.

In answer to our request for reports from California, page 741, there has been a flood of responses, all denying that there has been a heavy honey-flow in Southern California as reported in the newspaper clipping. They all assert that the crop has been light, and that there will be very little, if any, sage honey shipped eastward. In the orange district there have been some fair flows; but orange honey has never been any great factor in the eastern markets. As it is a very fine article, having a strong demand at home, it will probably be a scarce article away from California.

HIVE-LIFTING DEVICE.

We are experimenting with a hive-lifting device. We feel that there has been a long-felt want, as yet unsupplied by the dealer and manufacturer, for some simple effective device that will relieve the strain of lifting heavy supers, either for the purpose of putting empties under or for taking them off the hive. There are many ladies who would like to keep bees if they could avoid the lifting; and there are many men, either from age or ill health, who find it inadvisable to put any hard strain on the back. Your humble servant, E. R. R., strained his back years ago, and ever since has been unable to do any lifting of heavy weights. He has been testing some hive-lifting devices, and is now of the opinion that some one of them may be made very useful to those who have not the muscle and sinew of a strong vigorous man. We shall have more to say about these at another time.

TRAGIC DEATH OF AN OLD GLEANINGS CORRESPONDENT.

Our older readers will remember Mr. C. Davenport, of "Southern Minnesota," who used to write such racy, practical articles. He was not a prolific writer, but when he did write he commanded attention. He was one of the few whose communications are passed directly to the printers without reading the manuscript, as we had absolute confidence in the availability of his matter. Within a year or so we have not been favored with any thing from him, for he was a very busy man.

Mr. Davenport, or, rather, C. Davenport Monette, of Chatfield, Minn., for that was his real name and address, preferred to use a *nom de plume*, as he said his business was such that he would not be able to answer any correspondence except through the printed page.

We are now pained to observe through the papers of his tragic death, which occurred recently. He was burned to death in his own home, where he lived alone, and had the reputation of being a very successful and practical bee-keeper. No particulars are known of the manner or cause of the fire; but his charred bones were found just in front of what was the doorway, indicating that he had made an effort to escape. He was only 42 years old, and was one of the brightest bee-keepers that we had in our ranks. Our sympathies are extended to his parents, who lived but a short distance away.

"BEE DISEASES IN MASSACHUSETTS."

There has just been issued from the United States Department of Agriculture, Bureau of Entomology, Bulletin No. 75, Part 111, entitled "Bee Diseases in Massachusetts," by Burton N. Gates, Expert in Apiculture. As its title indicates, it has to do particularly with bee diseases, European (black), and old-fashioned or American foul brood.

A very interesting and instructive map is made a part of this bulletin, showing the distribution of both these diseases, not only in Massachusetts but in Connecticut, Vermont, and New Hampshire. European foul brood seems by all odds the most prevalent in both Massachusetts and Connecticut. The author thinks it was imported from York State, where it has been raging for years back.

The old-fashioned or American foul brood has been prevalent in both States for a considerable length of time, but is not of recent origin, Mr. Gates thinks.

In this connection it appears that the ravages of bee-moth have had something to do with the spread of disease, not because the moth is the primal source, but because a colony, when it is once reduced in strength by it, is made an easy victim of contagious diseases.

The spread of foul brood has also been brought about in part, says Mr. Gates, by bees kept in cucumber-greenhouses to fertilize the fruit-blossoms, for there are many of these establishments in Massachusetts. The bees, under these conditions, die in great numbers, with the result that the colony is weakened, and finally succumbs altogether. The hives with their combs are then thrown out where they are exposed, when another hive is put in its place to repeat the process. Of course, if there is any disease it is spread broadcast by the means. These greenhouse men do not, of course, know much about bee diseases, and are thus innocently one of the causes of spreading them over the State.

This whole bulletin is highly interesting, instructive, and valuable, and somehow we have the impression that it is the purpose of the Bureau to investigate other sections of the country in the same careful, painstaking way. If so, it will be the means of doing a great deal more good.

The map affords a very interesting study, and we hope to present a half-tone of it in these columns at an early date, if there are no objections.

Mr. Gates, under the direction of Dr. Phillips, is doing good work, and we hope the Bureau will see its way clear to make an investigation of other sections of the country. There is a very great need of it, for almost daily we are receiving samples of diseased brood from all parts of the country, with the request that we furnish information.

CAUCASIANS AT OUR SOUTH YARD; SOME OF THEIR UNDESIRABLE TRAITS; THEIR PROPENSITY TO SWARM, RAISE DRONES, AND TO BUILD QUANTITIES OF BRACE-COMBS.

WHEN we established our south yard last fall, we placed in it all of our Caucasian colonies and their crosses, as we thought it better to have them remote from our main breeding-yard at Medina, where we are rearing exclusively Italians. This

made in all between 35 and 40 colonies of the dark strain. In addition to this we put in this same yard about an equal number of Italians of various strains. It was our purpose to test both Caucasians and Italians side by side to determine their relative merits as to gentleness, honey-gathering qualities, etc.

So far we have refrained from offering any opinion until we could test the Caucasians for honey, any more than to state that we found them excessive breeders of drones (see page 683)—so much so that a few colonies of Caucasians in a yard with a lot of Italians, if not restrained with drone-traps, would breed out the yellow blood in very short order.

But how about their other qualities? We have not found them to be any gentler than the average run of Italians; neither have we found them to be any crosser. They will stand some kinds of banging in cool weather that the average Italians will not. They are slightly more nervous, and at times fly up *en masse* as if they were about to sting, but after all making little more than a big bluff. Colony by colony, season in and season out, with ordinary care one will receive as many stings from Caucasians as from Italians. But before we go further, we ought to state that we have in the yard two strains of Caucasians. We have never had any of the government strain of Caucasians, and therefore can not speak of those bees.

But you may ask how our Caucasians are for honey. Early in the season, and during the fore part of the flow, they ran neck and neck with our best Italians; and, what is more, the cappings of their combs were whiter than those made by the yellow bees; but this slight advantage is more than offset by their habit of daubing every thing with propolis. Brand-new frames they smear all over in three months' time, and make them look as if they were four or five years old.

THEIR SWARMING PROPENSITY.

We went down to look them over yesterday, July 7, and we were chagrined to find that something over 95 per cent of them had swarmed right when they were doing their very best work, while less than 5 per cent of the Italians, under precisely the same management, had swarmed. To say that we were surprised and disgusted is putting it mildly.

As we have previously explained, we have been working this yard alone, except a very little help from the boys. We ran the yard for extracted honey in shallow supers. Having calls for some Caucasian queens, pure and mated, we went down to the south yard and proceeded to fill our orders. We then looked over hive after hive of Caucasians with the above result—they swarmed. Fortunately we had drone-traps on all but two; and the virgins coming on made way with the old queens, and, of course, their colonies began to sulk. We did not, as perhaps we should have done, make an examination of the brood-nest; but we didn't know the Caucasians.

Year after year we worked hives of Italians on this same tier-up principle, for extracted honey, and we never found it necessary to go into the brood-nest. As we found the combs began to whiten we would add extra supers, putting emp-

ties under the partly filled ones up to about the middle of the flow, after that reversing the order. We expected, of course, the same procedure would work with the Caucasians, as it always had worked for us with the Italians, and as it worked this year under precisely the same conditions. Every one of the Caucasians and their crosses, with the exception of two, had swarmed, while we were up town attending to our office work—hives full of cells, some hatched and some not, and the colonies completely demoralized. The 35 colonies of Italians, in the same yard, with two single exceptions, went on taking in honey, and with those exceptions there was not a single colony that had a single cell in it or showed any indication of swarming.

You may say we ought to have known better, and that we ought not to have depended on surface indications at the entrance, at the tops, and under the sides of the combs, with *any* strain of bees. We admit that, had we gone through the brood-nests of the Caucasian colonies, cutting out the cells and the drone brood (and there were quantities of the latter), we might have checked the swarming to some extent. The fact remains, however, that we didn't have to do this with the Italians. No, they not only did not prepare to swarm but kept piling in the honey.

If this showing is a fair sample of Caucasians, and their swarming propensities can not readily be controlled in the production of *extracted* honey, what shall we say when we run them for the production of *comb*? If this yard had been exclusively Caucasian and its crosses, we might have laid the excessive swarming to the locality and season; but when it is understood that the 35 other colonies of Italians (except as mentioned) *in the same locality, in the same yard, and under precisely the same management, did not swarm, nor show any indications of it*, then we must perforce conclude that the difference was in the race.

But this is not all. The Caucasians are the worst bees we ever saw to plug in brace-combs. By this we mean spurs of wax between the *combs* and between the top-bars and not on top of them. There is occasionally a colony of Italians that will do this between the wide thick top-bars; but in our locality they are the exception, not the rule.

But even this is not all. The Caucasians stuck in brace-combs down between the frames in the very heart of the colony—so much so that it was very difficult to remove the frames. We will have some photos that will speak for themselves. While, of course, these brace-combs could be removed with the uncapping-knife, the act of drawing the combs out of the hive is very greatly impeded, to say nothing of the broken comb surfaces, and danger of killing queens and bees in the general stir-up.
